

The Apple IIc **Reference Manual** Volume 2

Customer Satisfaction

If you discover physical defects in the manuals distributed with an Apple product or in the media on which a software product is distributed. Apple will replace the documentation or media at no charge to you during the 90-day period after you purchased the product.

In addition, if Apple releases a corrective update to a software product during the 90-day period after you purchased the product period after you purchased the software, Apple will replace the applicable disks and documentation with the revised version at no charge to you during the six months after the date of purchase.

In some countries the replacement period may be different; check with your authorized Apple dealer. Return any item to be replaced with proof of purchase to Apple or an authorized Apple dealer.

Limitation on Warranties and Liability

Even though Apple has tested the software described in the manual and reviewed its contents, neither Apple nor its software suppliers make any warranty or representation; either express or implied, with respect to this manual or to the software described in this manual, their quality, performance, merchantability, or fitness for any particular purpose. As a result, this software and manual are sold "as is," and you the purchaser are assuming the entire risk as to their quality and performance. In no event will Apple or its software suppliers be liable for direct, indirect, incidental, or consequential damages resulting from any defect in the software or manual, even if they have been advised of the possibility of such damages. In particular, they shall have no liability for any programs or data stored in or used with Apple products, including the costs of recovering or reproducing these programs or data. Some states do not allow the exclusion or limitation of implied warranties or liability for incidental or consequential damages, so the above limitation or exclusion may not apply to you.

Copyright

This manual and the software (computer programs) described in it are copyrighted by Apple or by Apple's software suppliers, with all rights reserved. Under the copyright laws, this manual or the programs may not be copied, in whole or part, without the written consent of Apple, except in the normal use of the software or to make a backup copy. This exception does not allow copies to be made for others, whether or not sold, but all of the material purchased (with all backup copies) may be sold, given, or lent to another person. Under the law, copying includes translating into another language.

You may use the software on any computer owned by you, but extra copies cannot be made for this purpose. For some products, a multi-use license may be purchased to allow the software to be used on more than one computer owned by the purchaser, including a shared-disk system. (Contact your authorized Apple dealer for information on multi-use licenses.)

Product Revisions

Apple cannot guarantee that you will receive notice of a revision to the software described in the manual, even if you have returned a registration card received with the product. You should periodically check with your authorized Apple dealer.

Apple Computer, Inc. 1984 20525 Mariani Avenue Cupertino, California 95014

Warning

This equipment has been certified to comply with the limits for a Class B computing device, pursuant to Subpart J of Part 15 of FCC Rules. Only peripherals (computer input/output devices, terminals, printers, etc.) certified to comply with the Class B limit may be attached to this computer. Operation with non-certified peripherals is likely to result in interference to radio and TV reception.

preface

This volume, Volume 2 of the Apple IIc Reference Manual, contains nine appendixes, a bibliography, and a glossary.

Appendix A contains a description of the differences between the 6502 and the 65C02 microprocessors, plus a reprint of the manufacturer's data sheet for the 65C02 microprocessor.

Appendixes B and C contain tables of the important RAM, ROM, and hardware addresses in the Apple IIc. The reader can use these tables to find locations by address, the index to find them by label, the firmware listings to find them as defined and used, and the chapters to find them described in the context of their function.

Appendix B is a memory map of the Apple IIc, including detailed tables of page zero, page three, the screen holes, and the hardware page.

Appendix C lists the *published* firmware entry points, arranged by address, and indicates where in the manual they are described. The list includes I/O firmware (pages \$C1 through \$CF) and Monitor firmware (pages \$F0 through \$FF). For Applesoft interpreter firmware (pages \$D0 through \$EF), refer to the *Applesoft BASIC Programmer's Reference Manual*, Volumes 1 and 2.

Appendix D discusses what operating systems and languages run on the Apple IIc, and what features they do and do not use.

Appendix E describes how to use the Apple IIc's interrupt handling capabilities.

Appendix F contains an overview of the differences among the Apple II series computers.

xiii

Appendix G contains the keyboard layouts, code conversion tables, and external power supply characteristics of USA and international models of the Apple IIc.

Appendix H contains reference tables for code and number base conversion.

Appendix I contains a listing of the source code for the Monitor, enhanced video firmware, and input/output firmware contained in the Apple IIc. The listings do not include the built-in Applesoft interpreter, which is discussed in the *Applesoft BASIC Programmer's Reference Manual*.

The Bibliography lists articles and books containing additional information about the Apple IIc and related products.

The Glossary defines many of the technical terms used in this manual.

The 65C02 Microprocessor

This appendix contains a description of the differences between the 6502 and the 65C02 microprocessor. It also contains the data sheet for the NCR 65C02 microprocessor.

In the data sheet tables, execution times are specified in number of cycles. One cycle time for the Apple IIc equals 0.978 microseconds.

If you want to write programs that execute on all computers in the Apple II series, make sure your code uses only the subset of instructions present on the 6502.

A.1 Differences Between 6502 and 65C02

The data sheet lists the new instructions and addressing modes of the 65C02. This section supplements that information by listing the instructions whose execution times or results have changed.

A.1.1 Differing Cycle Times

In general, differences in execution times are significant only in time-dependent code, such as precise wait loops. Fortunately, instructions with changed execution times are few.

Table A-1 lists the instructions whose number of instruction execution cycles on the 65C02 is different from the number on the 6502.

Table A-1. Cycle Time Differences

Instruction/Mode	Opcode	6502 Cycles	65C02 Cycles
ASL Absolute, X	1E	7	6
DEC Absolute, X	DE	7	6
INC Absolute, X	FE	7	6
JMP (Absolute)	6C	5	6
LSR Absolute, X	5E	7	6
ROL Absolute, X	3E	7	6
ROR Absolute, X	7E	7	6

A.1.2 Differing Instruction Results

It is important to note that the BIT instruction when used in immediate mode (code \$89) leaves Processor Status Register bits 7 (N) and 6 (V) unchanged on the 65C02. On the 6502, all modes of the BIT instruction have the same effect on the Status Register: the value of memory bit 7 is placed in status bit 7, and memory bit 6 is placed in status bit 6. However, all BIT instructions on both versions of the processor set status bit 1 (Z) if the memory location contained a zero.

Also note that if the JMP indirect instruction (code \$6C) references an indirect address location that spans a page boundary, the 65C02 fetches the high-order byte of the effective address from the first byte of the next page, while the 6502 fetches it from the first byte of the current page. For example, JMP (\$2FF) gets ADL from location \$2FF on both processors. But on the 65C02, ADH comes from \$300; on the 6502, ADH comes from \$200.

A.2 Data Sheet

The remaining pages of this appendix are copyright 1982, NCR Corporation, Dayton, Ohio, and are reprinted with their permission.

GENERAL DESCRIPTION

The NCR CMOS 6502 is an 8-bit microprocessor which is software compatible with the NMOS 6502. The NCR65C02 hardware interfaces with all 6500 peripherals. The enhancements include ten additional instructions, expanded operational codes and two new addressing modes. This microprocessor has all of the advantages of CMOS technology: low power consumption, increased noise immunity and higher reliability. The CMOS 6502 is a low power high performance microprocessor with applications in the consumer, business, automotive and communications market.

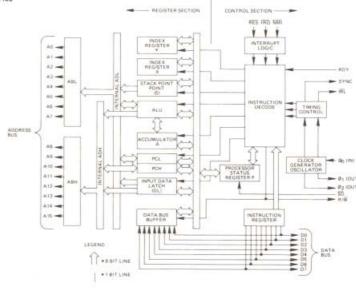

FEATURES

- Enhanced software performance including 27 additional OP codes encompassing ten new instructions and two additional addressing modes.
- · 66 microprocessor instructions.
- 15 addressing modes.
- 178 operational codes.
- 1MHz, 2MHz operation.
- Operates at frequencies as low as 200 Hz for even lower power consumption (pseudo-static: stop during \$\mathcal{Q}_2\$ high).
- Compatible with NMOS 6500 series microprocessors.
- 64 K-byte addressable memory.
- Interrupt capability.
- Lower power consumption.
 4mA @ 1MHz.
- +5 volt power supply.
- · 8-bit bidirectional data bus.
- Bus Compatible with M6800.
- Non-maskable interrupt.
- 40 pin dual-in-line packaging.
- 8-bit parallel processing
- Decimal and binary arithmetic.
- Pipeline architecture.
- · Programmable stack pointer.
- Variable length stack.
- Optional internal pullups for (RDY, IRQ, SO, NMI and RES)
- Specifications are subject to change without notice.

F2	SBC	Subtract memory from accumulator with borrow [(ZPG)]
92	STA	Store accumulator in memory [(ZPG)]

MICROPROCESSOR PROGRAMMING MODEL

FUNCTIONAL DESCRIPTION

Timing Contro

The timing control unit keeps track of the instruction cycle being monitored. The unit is set to zero each time an instruction fetch is executed and is advanced at the beginning of each phase one clock pulse for as many cycles as is required to complete the instruction. Each data transfer which takes place between the registers depends upon decoding the contents of both the instruction register and the timing control unit.

Program Counter

The 16-bit program counter provides the addresses which step the microprocessor through sequential instructions in a program.

Each time the microprocessor fetches an instruction from program memory, the lower byte of the program counter (PCL) is placed on the low-order bits of the address bus and the higher byte of the program counter (PCH) is placed on the high-order 8 bits. The counter is incremented each time an instruction or data is fetched from program memory.

Instruction Register and Decode

Instructions fetched from memory are gated onto the internal data bus. These instructions are latched into the instruction register, then decoded, along with timing and interrupt signals, to generate control signals for the various registers.

Arithmetic and Logic Unit (ALU)

All arithmetic and logic operations take place in the ALU including incrementing and decrementing internal registers (except the program counter). The ALU has no internal memory and is used only to perform logical and transient numerical operations.

Accumulator

The accumulator is a general purpose 8-bit register that stores the results of most arithmetic and logic operations, and in addition, the accumulator usually contains one of the two data words used in these operations.

Index Registers

There are two 8-bit index registers (X and Y), which may be used to count program steps or to provide an index value to be used in generating an effective address. When executing an instruction which specifies indexed addressing, the CPU fetches the op code and the base address, and modifies the address by adding the index register to it prior to performing the desired operation. Pre- or post-indexing of indirect addresses is possible (see

Stack Pointer

addressing modes).

The stack pointer is an 8-bit register used to control the addressing of the variable-length stack on page one. The stack pointer is automatically incremented and decremented under control of the microprocessor to perform stack manipulations under direction of either the program or interrupts (NMI and IRQ). The stack allows simple implementation of nested subroutines and multiple level interrupts. The stack pointer should be initialized before any interrupts or stack operations occur.

Processor Status Register

The 8-bit processor status register contains seven status flags. Some of the flags are controlled by the program, others may be controlled both by the program and the CPU. The 6500 instruction set contains a number of conditional branch instructions which are designed to allow testing of these flags (see microprocessor programming model).

NCR65C02 ADDRESSING MODES

Fifteen addressing modes are available to the user of the NCR65C02 microprocessor. The addressing modes are described in the following paragraphs:

Implied Addressing [Implied]
In the implied addressing mode, the address containing the operand is implicitly stated in the operation code of the instruction.

Accumulator Addressing [Accum]

This form of addressing is represented with a one byte instruction and implies an operation on the accumulator

Immediate Addressing [Immediate]

With immediate addressing, the operand is contained in the second byte of the instruction; no further memory addressing is required.

Absolute Addressing [Absolute]

For absolute addressing, the second byte of the instruc-tion specifies the eight low-order bits of the effective address, while the third byte specifies the eight high-order Therefore, this addressing mode allows access to the total 64K bytes of addressable memory.

Zero Page Addressing [Zero Page]

Zero page addressing allows shorter code and execution times by only fetching the second byte of the instruction and assuming a zero high address byte. The careful use of zero page addressing can result in significant increase in code efficiency

Absolute Indexed Addressing [ABS, X or ABS, Y]

Absolute indexed addressing it used in conjunction with X or Y index register and is referred to as "Absolute, X," and "Absolute, Y." The effective address is formed by adding the contents of X or Y to the address contained in the second and third bytes of the instruction, This mode allows the index register to contain the index or count value and the instruction to contain the base address. This type of indexing allows any location referencing and the index to modify multiple fields, resulting in reduced coding and execution time.

Zero Page Indexed Addressing [ZPG, X or ZPG, Y]

Zero page absolute addressing is used in conjunction with the index register and is referred to as "Zero Page, X" or "Zero Page, Y." The effective address is calculated by adding the second byte to the contents of the index register. Since this is a form of "Zero Page" addressing, the content of the second byte references a location in page zero. Additionally, due to the "Zero Page" addressing nature of this mode, no carry is added to the highorder eight bits of memory, and crossing of page boundaries does not occur

Relative Addressing [Relative]

Relative addressing is used only with branch instructions;

it establishes a destination for the conditional branch. The second byte of the instruction becomes the operand which is an "Offset" added to the contents of the program counter when the counter is set at the next instruction. The range of the offset is -128 to +127 bytes from the next instruction.

Zero Page Indexed Indirect Addressing [(IND, X)]

With zero page indexed indirect addressing (usually referred to as indirect X) the second byte of the instruction is added to the contents of the X index register; the carry is discarded. The result of this addition points to a memory location on page zero whose contents is the loworder eight bits of the effective address. The next memory location in page zero contains the high-order eight bits of the effective address. Both memory locations specifying the high- and low-order bytes of the effective address must be in page zero.

*Absolute Indexed Indirect Addressing [ABS(IND, X)] (Jump Instruction Only)

With absolute indexed indirect addressing the contents of the second and third instruction bytes are added to the X register. The result of this addition, points to a memory location containing the lower-order eight bits of the effective address. The next memory location contains the higher-order eight bits of the effective address.

Indirect Indexed Addressing [(IND), Y]

This form of addressing is usually referred to as Indirect, Y. The second byte of the instruction points to a memory location in page zero. The contents of this memory location are added to the contents of the Y index register, the result being the low-order eight bits of the effective address. The carry from this addition is added to the contents of the next page zero memory location, the result being the high-order eight bits of the effective address.

*Zero Page Indirect Addressing [(ZPG)]

In the zero page indirect addressing mode, the second byte of the instruction points to a memory location on page zero containing the low-order byte of the effective address. The next location on page zero contains the high-order byte of the effective address.

Absolute Indirect Addressing [(ABS)]

(Jump Instruction Only)

The second byte of the instruction contains the low-order eight bits of a memory location. The high-order eight bits of that memory location is contained in the third byte of the instruction. The contents of the fully speci-fied memory location is the low-order byte of the effec-tive address. The next memory location contains the high-order byte of the effective address which is loaded into the 16 bit program counter.

NOTE: * = New Address Modes

SIGNAL DESCRIPTION

Address Bus (A0-A15)

A0-A15 forms a 16-bit address bus for memory and I/O exchanges on the data bus. The output of each address line is TTL compatible, capable of driving one standard TTL load and 130pF

Clocks (\emptyset_0 , \emptyset_1 , and \emptyset_2) \emptyset_0 is a TTL level input that is used to generate the internal clocks in the 6502. Two full level output clocks are generated by the 6502. The \emptyset_2 clock output is in phase with Ø0. The Ø1 output pin is 180° out of phase with Ø0. (See timing diagram.)

Data Bus (D0-D7)

The data lines (D0-D7) constitute an 8-bit bidirectional data bus used for data exchanges to and from the device and peripherals. The outputs are three-state buffers capable of driving one TTL load and 130 pF.

Interrupt Request (IRQ)

This TTL compatible input requests that an interrupt sequence begin within the microprocessor. The $\overline{\mbox{IRO}}$ is sampled during Ø2 operation; if the interrupt flag in the processor status register is zero, the current instruction is completed and the interrupt sequence begins during 01. The program counter and processor status register are stored in the stack. The microprocessor will the may occur. At the end of this cycle, the program counter low will be loaded from address FFFE, and program counter high from location FFFF, transferring program control to the memory vector located at these addresses. The RDY signal must be in the high state for any inter rupt to be recognized. A 3K ohm external resistor should be used for proper wire OR operation,

Memory Lock (ML)

In a multiprocessor system, the ML output indicates the need to defer the rearbitration of the next bus cycle to ensure the integrity of read-modify-write instructions ML goes low during ASL, DEC, INC, LSR, ROL, ROR, TRB, TSB memory referencing instructions. This signal is low for the modify and write cycles.

Non-Maskable Interrupt (NMI)

A negative-going edge on this input requests that a nonmaskable interrupt sequence be generated within the microprocessor. The \overline{NMI} is sampled during \emptyset_2 ; the current instruction is completed and the interrupt sequence begins during 01. The program counter is loaded with the interrupt vector from locations FFFA (low byte) and FFFB (high byte), thereby transferring program control to the non-maskable interrupt routine.

Note: Since this interrupt is non-maskable, another NMI can occur before the first is finished. Care should be taken when using NMI to avoid this.

Ready (RDY)

This input allows the user to single-cycle the microprocessor on all cycles including write cycles. A negative transition to the low state, during or coincident with phase one (Ø1), will halt the microprocessor with the output address lines reflecting the current address being fetched. This condition will remain through a subsequent phase two (02) in which the ready signal is low. This feature allows microprocessor interfacing with low-speed memory as well as direct memory access (DMA).

Reset (RES)

This input is used to reset the microprocessor. Reset must be held low for at least two clock cycles after VDD reaches operating voltage from a power down, A positive transistion on this pin will then cause an initialization sequence to begin. Likewise, after the system has been operating, a low on this line of at least two cycles will cease microprocessing activity, followed by initialization after the positive edge on RES.

When a positive edge is detected, there is an initialization sequence lasting six clock cycles. Then the interrupt mask flag is set, the decimal mode is cleared, and the program counter is loaded with the restart vector from locations FFFC (low byte) and FFFD (high byte). This is the start location for program control. This input should be high in normal operation.

Read/Write (R/W)

This signal is normally in the high state indicating that the microprocessor is reading data from memory or I/O bus. In the low state the data bus has valid data from the microprocessor to be stored at the addressed memory

Set Overflow (SO)

A negative transition on this line sets the overflow bit in the status code register. The signal is sampled on the trailing edge of Ø1.

Synchronize (SYNC)

This output line is provided to identify those cycles dur-ing which the microprocessor is doing an OP CODE fetch. The SYNC line goes high during Ø10f an OP CODE fetch and stays high for the remainder of that cycle. If the RDY line is pulled low during the Ø1 clock pulse in which SYNC went high, the processor will stop in its current state and will remain in the state until the RDY line goes high. In this manner, the SYNC signal can be used to control RDY to cause single instruction execu-

Memory Map

Appendix H explains the general rules and tables for converting numbers from one of these forms to another. For memory map diagrams, refer to Chapter 2. Figure 2-2 is an overall memory map, Figure 2-3 is a map of bank-switched memory, and Figure 2-11 is a map of the 48K memory space.

This appendix lists all important RAM and hardware locations in address order and describes them briefly. It also provides cross-references to the section of the manual where they are described further. Appendix C contains a similar list for important firmware addresses.

The tables in this appendix list addresses in either two or three forms: the hexadecimal form (preceded by a dollar sign) for use in assembly language; the decimal form for use in Applesoft BASIC; and (for numbers greater than 32767) the complementary decimal value for use in Apple Integer BASIC.

B.1 Page Zero

For Monitor zero page usage, refer to the firmware listings. For zero page use by the languages and operating systems, refer to the appropriate reference manuals.

Table B-1 lists the zero page addresses in hexadecimal and decimal form, followed by symbols denoting the firmware or system software that uses them.

- · M denotes the Monitor.
- · A denotes Applesoft BASIC.
- I denotes Integer BASIC.
- D denotes DOS.
- P denotes ProDOS. Locations whose contents ProDOS saves and restores afterward have a P in parentheses, indicating that ProDOS has no net effect on them.

Table B-1. Zero Page Use

B.2 Page Three

Most of page 3 is available for small machine-language programs or any other use your program might put it to. The built-in Monitor uses the top sixteen addresses of page 3, as shown in Table B-2; the XFER routine (section 2.5.3) uses locations \$3ED and \$3EE. If you are using DOS or ProDOS, it also uses the 32 locations \$3D0 through \$3EF.

Table B-2. Page 3 Use

Hex	Dec	Section	Use
\$3F0 \$3F1	1008 1009	2.6.4	Address of BRK request handler (normally \$59, \$FA)
\$3F2 \$3F3	1010 1011	2.6.4 &	Reset vector
\$3F4	1012	2.6.4	Power-up byte (see text)
\$3F5 \$3F6 \$3F7	1013 1014 1015		Jump instruction to Applesoft &-command handler (initially \$4C, \$58, \$FF)
\$3F8 \$3F9 \$3FA	1016 1017 1018	10.6.4	Jump instruction to user CONTROL-Y command handler
\$3FB \$3FC \$3FD	1019 1020 1021		Jump instruction to NMI interrupt handler (not used by Apple IIc)
\$3FE \$3FF	1022 1023	2.6.4	Address of user IRQ interrupt handler

B.3 Screen Holes

One result of the way the Apple IIc hardware maps display memory on the screen is that groups of eight memory addresses are left over in sixteen areas of the text and low-resolution display pages—eight areas in main RAM and eight in auxiliary RAM. The firmware uses for these 128 bytes are shown in Tables B-3 and B-4, with cross-references to the section numbers where they are described.

Table B-3. Main Memory Screen Hole Allocations

Hex	Dec	Section	Description
\$478	1144	9.1.5	Mouse port: low byte of clamping minimum
\$479	1145	7.5	Reserved for serial port 1

B.4 The Hardware Page

Tables B-5 through B-9 list all the hardware locations available for use in the Apple IIc. These tables have a column at the left that is not present in other tables. This column, labeled RW, indicates the action to take at a particular location.

- · R means read.
- RR means read twice in succession.
- R7 means read the byte and then check bit 7; in the use column, "see if..." refers to the condition represented by bit 7 = 1, unless otherwise specified. Bit 7 has a value of \$80, so if the contents of the location are greater than or equal to \$80, the bit is on.

Another way to test bit 7 (the sign bit) is with a BIT instruction, followed by BPL (bit 7 was 0) or BMI (bit 7 was 1).

- R/W means to either read or write. For writing, the value is unimportant.
- W means to write only. The value is unimportant.
- N means not to read or write, because the location is reserved.

An address of the form \$C00x means the sixteen locations from \$C000 through \$C00F. Labels, when they are shown, are simply memory aids. Some of them correspond to the labels at those addresses in the firmware, others do not. Your program will have to assign a label for it anyway.

Table B-5. Addresses \$C000 Through \$C03F

RW	Hex	Dec	Neg Dec	Label	Section	Use
				KSTRB	4.1	Read keyboard data (bits 0-6) and strobe (bit 7)

Important Firmware Locations

This appendix lists all significant firmware addresses: entry points, locations containing the addresses of entry points, and locations where machine and device identification bytes reside.

Warning

The Monitor firmware entry points are the only published entry points in the sense that they are the only ones that will remain in the same locations in future Apple II series computers.

The firmware protocol identification bytes and offsets will work with other Apple II series computers only if used as directed (section 3.4.2).

C.1 The Tables

Appendix H contains tables and examples of the derivation of each form of address from either of the other forms.

This appendix supplements the chapter text by specifying three forms of each address: hexadecimal, decimal, and complementary (negative) decimal.

In these tables, some of the addresses are followed by a label of the location. These labels are listed only to assist you in finding the named location in the firmware listings, or in remembering the function found at the address. The Apple IIc contains no global label table: your program must assign its own labels to the addresses as required.

There are several types of information at these firmware addresses: actual entry points (labeled *entry*), the low-order byte of an entry point (labeled *offset*), a device or machine

identification byte (labeled *ident*), indicators (labeled *indic*) specifying whether there are optional routines, vector addresses (labeled *vector*), and an RTS instruction location.

The column labeled *Section* contains the number of the section that describes the item. If there is no description except in a table in this appendix, a section number is not listed.

Each input/output port has an associated protocol table, as shown in Tables C-1 through C-4. Many of the bytes (labeled *offset*) in the protocol tables are the low-order bytes of addresses of I/O routines for the ports; the high-order byte of these addresses must be \$Cn (where *n* is the port number). This structure is explained in Chapter 3. Although your program must perform some extra processing to use these tables, the benefit is simplified compatible port and slot I/O for all Apple II series machines.

C.2 Port Addresses

Table C-1. Serial Port 1 Addresses

Hex	Dec	Neg Dec Label	Type	Section	Description
\$C100	49408	-16128	entry	3.1.1	Main port 1 entry point
\$C105	49413	-16123	ident	3.4.2	ID byte (\$38)
\$C107	49415	-16121	ident	3.4.2	ID byte (\$18)
\$C10B	49419	-16117	ident	3.4.2	Firmware card signature (\$01)
\$C10C	49420	-16116	ident	3.4.2	Super Serial Card ID (\$31)
\$C10D	49421	-16115	offset	7.4	Low-order PINIT address
\$C10E	49422	-16114	offset	7.4	Low-order PREAD address
\$C10F	49423	-16113	offset	7.4	Low-order PWRITE address
\$C110	49424	-16112	offset	7.4	Low-order PSTATUS address
\$C111	49425	-16111	indic	3.4.2	Non-zero: no optional routines

Table C-2. Serial Port 2 Addresses

Hex	Dec	Neg Dec Label	Type	Section	Description
\$C200	49664	-15872	entry	3.1.1	Main port 2 entry point
\$C205	49669	-15867	ident	3.4.2	ID byte (\$38)
\$C207	49671	-15865	ident	3.4.2	ID byte (\$18)
\$C20B	49675	-15861	ident	3.4.2	Firmware card ID (\$01)
\$C20C	49676	-15860	ident	3.4.2	Super Serial Card ID (\$31)
\$C20D	49677	-15859	offset	8.4	Low-order PINIT address
\$C20E	49678	-15858	offset	8.4	Low-order PREAD address
\$C20F	49679	-15857	offset	8.4	Low-order PWRITE address
\$C210	49680	-15856	offset	8.4	Low-order PSTATUS address
\$C211	49681	-15855	indic	3.4.2	Non-zero: no optional routines

Table C-3. Video Firmware Addresses

Hex	Dec	Neg Dec	Label		Туре	Section	Description
\$C300	49920	-15616			entry	3.1.1	Main video entry point (output only)
\$C305	49925	-15611	C3KEYIN		ident	3.4.2	ID byte (\$38)
\$C307	49927	-15609	C3COUT1		ident	3.4.2	ID byte (\$18)
\$C30B	49931	-15605			ident	3.4.2	Firmware card signature (\$01)
\$C30C	49932	-15604			ident	3.4.2	80-column card ID (\$88)
\$C30D	49933	-15603			offset	5.9	Low-order PINIT address
\$C30E	49934	-15602		1.0	offset	5.9	Low-order PREAD address
\$C30F	49935	-15601			offset	5.9	Low-order PWRITE address
\$C310	49936	-15600			offset	5.9	Low-order PSTATUS address
\$C311	49937	-15599	MOVEAUX		entry	2.5.3	Routine for main/auxiliary control swapping (Also called AUXMOVE)

Table C-4. Mouse Port Addresses

Hex	Dec	Neg Dec	Label	Type	Section	Description
\$C400	50176	-15360		entry		Main mouse entry point
\$C405	50181	-15355		ident	3.4.2	ID byte (\$38)
\$C407	50183	-15353		ident	3.4.2	ID byte (\$18)
\$C40B	50187	-15349		ident	3.4.2	Firmware card signature (\$01)
\$C40C	50188	-15348		type	3.4.2	X-Y pointing device ID (\$20)
\$C40D	50189	-15347		offset	9.1.4	Low-order PINIT address
\$C40E	50190	-15346		offset	9.1.4	Low-order PREAD address
\$C40F	50191	-15345		offset	9.1.4	Low-order PWRITE address
\$C410	50192	-15344		offset	9.1.4	Low-order PSTATUS address
\$C411	50193	-15343		indic	3.4.2	Optional routines follow (\$00)
\$C412	50194	-15342	SETMOUSE	offset	9.1.4	Low-order SETMOUSE address
\$C413	50195	-15341	SERVEMOUSE	offset	9.1.4	Low-order SERVEMOUSE address
\$C414	50196	-15340	READMOUSE	offset	9.1.4	Low-order READMOUSE address
\$C415	50197	-15339	CLEARMOUSE	offset	9.1.4	Low-order CLEARMOUSE address
\$C416	50198	-15338	POSMOUSE	offset	9.1.4	Low-order POSMOUSE address
\$C417	50199	-15337	CLAMPMOUSE	offset	9.1.4	Low-order CLAMPMOUSE address
\$C418	50200	-15336	HOMEMOUSE	offset	9.1.4	Low-order HOMEMOUSE address
\$C419	50201	-15335	INITMOUSE	offset	9.1.4	Low-order INITMOUSE address

C.3 Other Video and I/O Firmware Addresses

Miscellaneous firmware addresses are listed in Table C-5.

Table C-5. Apple IIc Enhanced Video and Miscellaneous Firmware

Hex	Dec	Neg Dec	Label	Type	Section	Description
\$C600	50688	-14848	NEWIRQ	entry	6.1	Disk drive firmware entry point
\$C700	50944	-14592		entry	6.2	External disk startup routine
\$C803	51203	-14333		entry	E.1	IRQ handling routine

C.4 Applesoft BASIC Interpreter Addresses

The addresses of Applesoft BASIC entry points are listed in the Applesoft BASIC Programmer's Reference Manual. The Applesoft interpreter occupies ROM addresses from \$D000 through \$F7FF.

C.5 Monitor Addresses

Table C-6 lists the Monitor entry points, machine identifier bytes, interrupt vectors, and the address of a known RTS instruction.

Table C-6. Apple IIc Monitor Entry Points and Vectors

Hex	Dec	Neg Dec	Label	Туре	Section	Description
\$F800	63488	-2048	PLOT	entry	5.8	Plots a low-resolution block
\$F819	63513	-2023	HLINE	entry	5.8	Draws low-resolution horizontal line
\$F828	63528	-2008	VLINE	entry	5.8	Draws low-resolution vertical line
\$F832	63538	-1998	CLRSCR	entry	5.8	Clears low-resolution screen
\$F836	63542	-1994	CLRTOP	entry	5.8	Clears top 40 low-resolution lines
\$F864	63588	-1948	SETCOL	entry	5.8	Sets low-resolution color (Table 5-4)
\$F871	63601	-1935	SCRN		5.8	Reads color of low-resolution block
\$10/1	03001		SCHIN	entry	3.0	Heads color of low-resolution block
\$F941	63809	-1727	PRNTAX	entry	5.8	Displays (A) and (X) in hex
\$F94A	63818	-1718	PRBL2	entry	5.8	Sends (X) blanks to output
\$FA47	63845	-1691	NEWBRK	entry	E.2	Apple IIc break handler
\$FA62	64098	-1438	RESET	entry	2.6	Hardware reset routine
\$FB1E	64286	-1250	PREAD	entry	9.2	Reads hand control position
\$FB6F	64367	-1169	SETPWRC	entry	2.6.4	Routine to create power-up byte
\$FBB3	64435	-1101	OLII WITO	ident	F.1.2	Machine identification byte
\$FBC0	64448	-1088		ident	F.1.2	Machine identification byte
\$FBDD	64477	-1059	BELL1	entry	4.2.2	Sends 1 kHz beep to speaker
\$LDDD.	044//	-1059	DELLI	entry	4.2.2	Sends 1 KHZ beep to speaker
\$FC42	64578	-958	CLREOP	entry	5.8	Clears from cursor to bottom
\$FC58	64600	-936	HOME	entry	5.8	Clears; cursor to upper left
\$FC9C	64668	-868	CLREOL	entry	5.8	Clears from cursor to end of line
\$FC9E	64670	-866	CLEOLZ	entry	5.8	Clears from BASL to end of line
\$FCA8	64680	-856	WAIT	entry		Delays for time specified by (A)
\$FD0C	64780	-756	RDKEY	entry	3.2.1	Displays cursor, jumps to (KSW)
\$FD1B	64795	-741	KEYIN	entry	3.2.2	Waits for keypress, reads key
\$FD35	64821	-715	RDCHAR	entry	4.1.2	Gets input, interprets ESC codes
\$FD67	64871	-665	GETLNZ	entry	4.1.2	Sends CR to output, goes to GETLN
\$FD6A	64874	-662	GETLN	entry	3.2.3	Displays prompt, gets input line
\$FD6F	64879	-657	GETLN1	entry	4.1.2	No prompt; gets input line
\$FD8B	64907	-629	CROUT1	entry	5.8	Clears to end of line, calls CROUT
\$FD8E	64910	-626	CROUT	entry	5.8	Sends CR to output
		-550	PRBYTE		5.8	Sends (A) to output
\$FDDA	64986			entry	5.8	Displays low nibble of (A) in hex
\$FDE3	64995	-541	PRHEX	entry		
\$FDED	65005	-531	COUT	entry	3.3.1	Jumps to (CSW)
\$FDF0	65008	-528	COUT1	entry	3.3.2	Displays (A), advances cursor
\$FE2C	65068	-468	MOVE	entry		Copies (memory) elsewhere
\$FE36	65078	-458	VERIFY	entry		Compares two blocks of memory
\$FF2D	65325	-211	PRERR	entry	5.8	Sends ERR to output; beeps
\$FF3A	65338	-198	BELL	entry	4.2.2	Sends CONTROL-G to output
\$FF3F	65343	-193	IOREST	entry		Loads (\$45-\$49) into registers
SFF4A	65354	-182	IOSAVE	entry		Stores (A,X,Y,P,S) at \$45-\$49
\$FF58	65368	-168	IORTS	RTS		Location of known RTS instruction
\$FF69	65385	-151	(Monitor)	entry	10.1	Standard Monitor entry point
\$FFFA	65530	-6		vector		Low-order NMI vector (unused)
\$FFFB	65531	-5		vector		High-order NMI vector (unused)
\$FFFC	65532	-4		vector		Low-order RESET vector (\$62)
		-4				High-order RESET vector (\$FA)
\$FFFD	65533		IDOVECT	vector		
\$FFFE	65534	-2	IRQVECT	vector		Low-order IRQ vector (\$03)
\$FFFF	65535	-1		vector		High-order IRQ vector (\$CB)

Operating Systems and Languages

This appendix is an overview of the characteristics of operating systems and languages when run on the Apple IIc. It is not intended to be a full account. For more information, refer to the manuals that are provided with each product.

D.1 Operating Systems

This section discusses the operating systems that the Apple IIc does and does not work with.

D.1.1 ProDOS

ProDOS is the preferred disk operating system for the Apple IIc. It supports startup from the external disk drive, interrupts, and all other hardware and firmware features of the Apple IIc.

D.1.2 DOS

The Apple IIc works with DOS 3.3. Its disk drive support hardware and firmware can also access DOS 3.2 disks by using the *BASICS* disk. However, neither version of DOS takes full advantage of the features of the Apple IIc. DOS support is provided only for the sake of Apple II series compatibility.

D.1.3 Pascal Operating System

Version 1.2 of the Pascal Operating System uses the 80/40 switch and the interrupt features of the Apple IIc, while remaining compatible with the other Apple II series computers.

While the Apple IIc works with Pascal 1.1, this version of the Pascal Operating System does not use the 80/40 switch or handle interrupts.

The Apple IIc does not work with Pascal 1.0, because the input/output firmware entry points are rigidly defined (rather than being accessed via a table), and the firmware does not support these entry points.

D.1.4 CP/M

CP/M, and any other operating system that requires an interface card, will not work on the Apple IIc.

D.2 Languages

For further information about these languages, refer to the manuals that came with them.

Use the appendixes to make or find decimal conversions.

Appendix H has tables and examples to help you convert numbers between hexadecimal, decimal, and negative (complementary) decimal. All the addresses listed in Appendixes B and C—screen holes, hardware addresses, firmware entry points,

and so on-are given in all three

numeric forms.

This section discusses special techniques to use, and characteristics to be aware of, when using Apple programming languages with the Apple IIc. It is also a guide to using this reference manual with these languages.

D.2.1 Applesoft BASIC

The focus of the chapters in this manual is assembly language, and so most addresses and values are given in hexadecimal notation.

Use a PEEK in BASIC (instead of LDA in assembly language) to read a location, and a POKE (instead of STA) to write to a location. If you read a hardware address from a BASIC program, you get a value between 0 and 255. Bit 7 has a value of 128, so if a soft switch is on, its value will be equal to or greater than 128; if the switch is off, the value will be less than 128.

D.2.2 Integer BASIC

Unless you load a version of DOS into your Apple IIc, you will not have Integer BASIC available inside the machine. ProDOS does not support Integer BASIC.

D.2.3 Pascal Language

The Pascal language works on the Apple IIc under versions 1.1 and 1.2 of the Pascal Operating System. However, for best performance, use Pascal version 1.2.

D.2.4 FORTRAN

FORTRAN works under version 1.1 of the Pascal Operating System which, as explained in section D.1.3, does not detect or use certain Apple IIc features, such as the 80/40 switch or auxiliary memory. Therefore, FORTRAN does not take advantage of these features either.

Interrupts

This appendix presents a unified account of the sources of interrupts on the Apple IIc, how the firmware handles the interrupts, and how to use interrupt-driven features directly in those rare cases when the firmware cannot meet your needs.

Warning

If you use interrupt hardware directly, rather than using the built-in interrupt-handling firmware, compatibility with possible future Apple II series computers or revisions cannot be guaranteed.

E.1 Introduction

This section orients you to interrupts and their effects on the Apple IIc hardware.

E.1.1 What Is an Interrupt?

On a computer, an interrupt is a signal that abruptly causes the computer to stop what it is currently doing and immediately attend to an important time-dependent task. For example, the Apple IIc mouse sends an interrupt to the computer every time it moves. This is necessary because unless the mouse is read shortly after it moves, the signal indicating its direction is lost.

When an interrupt occurs, control passes to an interrupt handler, which must record the exact state of the computer at the moment of the interrupt, determine the source of the interrupt, and take appropriate action. It is important that the

computer preserve a *snapshot* of its state when interrupted, so that when it continues later with what it had been doing, those conditions can be restored.

E.1.2 Interrupts on Apple II Computers

Interrupts have not always been fully supported on the Apple II. All versions of Apple's DOS, as well as the Monitor program, rely on the integrity of location \$45, which the built-in interrupt handler has always destroyed by saving the accumulator in it. Most versions of Pascal simply do not work with interrupts enabled.

The Apple IIc built-in interrupt handler now saves the accumulator on the stack instead of in location \$45. Thus both DOS and the Monitor work with interrupts on the Apple IIc.

If, however, you want software that uses interrupts to work on the Apple IIe and the Apple II Plus, you must use either ProDOS, Apple's new enhanced disk operating system, or Pascal 1.2. Both operating systems have full interrupt support built in.

Interrupts are effective only if they are enabled most of the time. Interrupts that occur while interrupts are disabled cannot be detected. Due to the critical timing of disk read and write operations, Pascal, DOS, and ProDOS turn off interrupts while accessing the disk. Thus it is important to remember that while a disk drive is being accessed, all sources of interrupts discussed below are turned off.

On the Apple IIe only, interrupts are periodically turned off while 80-column screen operations are being performed. This is most noticeable while the screen is scrolling. Also, most peripheral cards used in the Apple IIe disable interrupts while reading and writing.

E.1.3 Interrupt Handling on the 65C02

From the point of view of the 65C02, there are three possible causes of interrupts.

- If 65C02 interrupts are not masked (that is, the CLI instruction has been used), the IRQ line on the microprocessor can be pulled low. This is the standard technique by which a device indicates that it needs immediate attention.
- The processor executes a break (BRK, opcode \$00) instruction.
- 3. A non-maskable interrupt (NMI) occurs. Because the NMI line in the Apple IIc's 65C02 is not used, this never happens.

Options 1 and 2 cause the 65C02 to save the current program counter and status byte on the stack and then jump to the routine whose address is stored in \$FFFE and \$FFFF. The sequence performed by the 65C02 is:

- 1. If IRQ, finish executing the current instruction. (If BRK, current instruction is already finished.)
- 2. Push high byte of program counter onto stack.
- 3. Push low byte of program counter onto stack.
- 4. Push program status byte onto stack.
- Jump to address stored in \$FFFE, \$FFFF, that is, JMP (\$FFFE).

The different sources of interrupt signals are discussed below.

E.1.4 The Interrupt Vector at \$FFFE

In the Apple IIc computer there are three separate regions of memory that contain address \$FFFE: the built-in ROM, the bank-switched memory in main RAM, and the bank-switched memory in auxiliary RAM. The vector at \$FFFE in the ROM points to Apple IIc's built-in interrupt handling routine. Due to the complexity of interrupts in the Apple IIc, it is recommended that you use it rather than writing your own interrupt handling routine.

When you initialize the mouse or serial communication firmware, copies of the ROM's interrupt vector are placed in the interrupt vector addresses in both main and auxiliary bank-switched

memory. If you plan to use interrupts and the bank-switched memory without the mouse or communication firmware, you must copy the ROM's interrupt vector yourself.

E.2 The Built-in Interrupt Handler

The built-in interrupt handler is responsible for determining whether a BRK or an IRQ interrupt occurred. If it was an IRQ interrupt, it decides whether the interrupt should be handled internally, handled by the user, or simply ignored.

The built-in interrupt handling routine records the current memory configuration, then sets up its own standard memory configuration so that a user's interrupt handler knows the precise memory configuration when it is called.

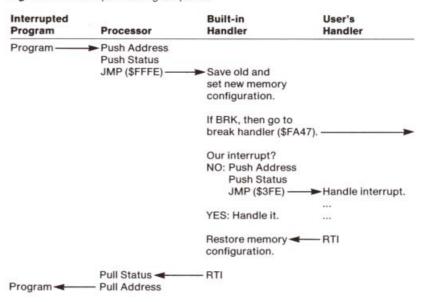

Next the handler checks to see if the interrupt was caused by a break instruction, and if it was, handles it as described in section E.4.

If the interrupt was not caused by a BRK, the handler checks for interrupts that it knows how to handle (for example, a properly initialized mouse) and handles them.

Depending on the state of the system, it either ignores other interrupts, or passes them to a user's interrupt handling routine whose address is stored at \$3FE and \$3FF of main memory.

After handling an interrupt itself, or after the user's handler returns (with an RTI), the built-in interrupt handler restores the memory configuration, and then does an RTI to restore processing to where it was when the interrupt occurred. Figure E-1 illustrates this whole process. Each of the steps is explained in detail in the sections that follow.

Figure E-1. Interrupt-Handling Sequence

E.2.1 Saving the Memory Configuration

The built-in interrupt handler saves the state of the system, and sets it to a known state according to these rules:

- If 80STORE and PAGE2 are on, then it switches in Text Page 1 (PAGE2 off) so that main screen holes are accessible.
- It switches in main memory for reading (RAMRD off).
- It switches in main memory for writing (RAMWRT off).
- It switches in ROM addresses \$D000-\$FFFF for reading (RDLCRAM off).
- It switches in main stack and zero page (ALTZP off).
- It preserves the auxiliary stack pointer, and restores the main stack pointer (see section E.2.2).

Note: Because main memory is switched in, all memory addresses used later in this appendix are in main memory unless otherwise specified.

E.2.2 Managing Main and Auxiliary Stacks

Because the Apple IIc has two stack pages, the firmware has established a convention that allows the system to be run with two separate stack pointers. Two bytes in the auxiliary stack page are to be used as storage for inactive stack pointers: \$100 for the main stack pointer when the auxiliary stack is active, and \$101 for the auxiliary stack pointer when the main stack is active.

When a program that uses interrupts switches in the auxiliary stack for the first time, it should place the value of the main stack pointer at auxiliary stack address \$100, and initialize the auxiliary stack pointer to \$FF (the top of the stack). When it subsequently switches from one stack to the other, it should save the current stack pointer before loading the pointer for the other stack.

When an interrupt occurs while the auxiliary stack is switched in, the current stack pointer is stored at \$101, and the main stack pointer is retrieved from \$100. Then the main stack is switched in for use. After the interrupt has been handled, the stack pointer is restored to its original value.

E.3 User's Interrupt Handler at \$3FE

Screen hole locations can be set up to indicate that the user's interrupt handler should be called when certain interrupts occur. To use such a routine, place its address at \$3FE and \$3FF in main memory, low byte first.

The user's interrupt handler should do the following:

- Verify that the interrupt came from the expected source. The following sections describe how this should be done for each interrupt source.
- · Handle the interrupt as desired.
- Clear the interrupt, if necessary. The following sections describe how to clear the interrupts.
- · Return using an RTI instruction.

If your interrupt handler needs to know the memory configuration at the time of the interrupt, it can check the encoded byte stored four bytes down on the stack. This byte is explained in section E.4.

In general there is no guaranteed response time for interrupts. This is because the system may be doing a disk operation, which could last for several seconds.

Once the built-in interrupt handler has been called, it takes about 250 to 300 microseconds for it to call your interrupt handling routine. After your routine returns, it takes 40 to 140 microseconds to restore memory and return to the interrupted program.

If memory is in the standard state when the interrupt occurs, the total overhead for interrupt processing is about 150 microseconds less than if memory is in the worst possible state (80STORE and PAGE2 on, auxiliary memory switched in for reading and writing, auxiliary bank-switched memory page 2 switched in for reading and writing).

E.4 Handling Break Instructions

After the interrupt handler has set the memory configuration, it checks to see if the interrupt was caused by a BRK (opcode \$00) instruction. (If it was, bit 4 of the processor status byte is a one). If so, it jumps to a break handling routine, which saves the state of the computer at the time of the break as follows.

Information	Location
Program counter (low byte)	\$3A
Program counter (high byte)	\$3B
Encoded memory state	\$44
Accumulator	\$45
X register	\$46
Y register	\$47
Status register	\$48

Finally the break routine jumps to the routine whose address is stored at \$3F0 and \$3F1.

The encoded memory state in location \$44 can be interpreted as follows:

Bit 7	=	0	
Bit 6	=	1	if 80STORE and PAGE2 both on
Bit 5	=	1	if auxiliary RAM switched in for reading
Bit 4	=	1	if auxiliary RAM switched in for writing
Bit 3	$r^{\alpha}=r^{\alpha}$	1	if bank-switched RAM being read
Bit 2	=	1	if bank-switched \$D000 page 1 switched in
Bit 1	=	1	if bank-switched \$D000 page 2 switched in
Bit 0	=	0	

E.5 Sources of Interrupts

The Apple IIc can receive interrupts from many different sources. Each source is enabled and used slightly differently from the others. There are two basic classes of interrupt sources: those associated with use of the mouse, and those associated with the two 6551 ACIA circuits (the chips that control serial communication).

The interrupts that are associated with the mouse are these:

- An interrupt can be generated when the mouse is moved in the horizontal (X) direction.
- An interrupt can be generated when the mouse is moved in the vertical (Y) direction.
- An interrupt can be generated every 1/60 second. This is called the vertical blanking (VBL) interrupt, and is synchronized with a signal used for the video display.
- Using the firmware, interrupts can be generated when the mouse button is pressed.

The interrupts that are associated with the ACIAs are these:

- An interrupt can be generated when a key is pressed. The firmware can use this interrupt to buffer keystrokes, or it can pass the interrupt on to the user.
- An interrupt can be generated by a device attached to the external disk drive port. The firmware can pass this interrupt on to the user.
- An interrupt can be generated when either ACIA has received a byte of data from its port. The firmware can use this interrupt to buffer data or it can pass the interrupt on to the user.
- An interrupt can be generated when pin 5 of either serial port changes state (device ready/not ready to accept data).
 When the serial firmware is active, this interrupt is absorbed; however, the serial firmware uses the signal to decide whether or not to transmit the next byte of data.
- An interrupt can be generated when either ACIA is ready to accept another character to be transmitted. When the serial firmware is active, this interrupt is absorbed; however, the serial firmware uses the signal to decide whether or not to transmit the next byte of data.
- An interrupt is generated when the keyboard strobe is cleared. The firmware absorbs this interrupt.

E.6 Firmware Handling of Interrupts

The following sections discuss the various sources of interrupts and how they should be used in conjunction with the built-in interrupt handler.

E.6.1 Firmware for Mouse and VBL

As described in Chapter 9, the mouse can be initialized (by the SETMOUSE call) to nine different modes that enable one or more sources of interrupts. In transparent mode, the interrupts are entirely handled by the built-in interrupt handler; the other modes require a user-installed interrupt handler.

When the mouse is initialized, the interrupt vector is copied to addresses \$FFFE and \$FFFF in main and auxiliary bank-switched RAM. This permits mouse interrupts with any memory configuration.

When the mouse is active, possible sources of interrupts are:

- · Mouse movement in the X direction
- · Mouse movement in the Y direction
- · Change of state of the button
- · Rising edge of the vertical blanking signal.

When an interrupt occurs, the built-in interrupt handler determines whether that particular interrupt source was enabled (by the SETMOUSE call). If so, the user's interrupt handler, whose address is stored at \$3FE, is called.

The user's interrupt handler should first call SERVEMOUSE to determine the source of the interrupt. This call updates the mouse status byte at \$77C and returns with the carry bit clear if mouse movement, button, or vertical blanking was the source of the interrupt.

The values of this mouse status byte at \$77C are as follows:

Bit	1 means that
3	Interrupt was from vertical blanking
2	Interrupt was from button
1	Interrupt was from mouse movement

If the interrupt was due to mouse movement or button, the user's interrupt handler should then do a call to READMOUSE. This causes the mouse coordinates and status to be updated as follows:

\$47C	Low byte of X coordinate
\$4FC	Low byte of Y coordinate
\$57C	High byte of X coordinate
\$5FC	High byte of Y coordinate

\$77C			Button and movement status
Bit	Me	ans	
7	0	=	button up; 1 = button down
6	0	i=0	button up on last READMOUSE
3070	1	=	button down on last READMOUSE
5	0	=	no movement since last READMOUSE
	1	=	movement since last READMOUSE
2.1	alv	ave s	et to 0 (interrupt cleared)

always set to 0 (interrupt cleared) 3-1

After the interrupt has been handled, the routine should terminate with an RTI.

As already mentioned, interrupts may be missed during disk accesses.

If you turn on mouse interrupts without initializing the mouse, the built-in interrupt handler will absorb the interrupts. If you want to handle mouse interrupts yourself, you must write your own interrupt handler and place vectors to it at addresses \$FFFE and \$FFFF in bank-switched RAM. Interrupts will be ignored whenever the \$D000-\$FFFF ROM is switched in.

E.6.2 Firmware for Keyboard Interrupts

The Apple IIc hardware is able to generate an interrupt when a key is pressed. The firmware is able to buffer up to 128 keystrokes, completely transparently, when properly enabled to do so. It saves them in the second half of page 8 of auxiliary memory. After the buffer is full, subsequent keystrokes are ignored. Because interrupts are only generated when keypresses occur, characters generated by the auto-repeat feature are not buffered. They can, however, be read when the buffer is empty.

Once keyboard buffering has been turned on, the next key should be read by calling RDKEY (\$FD0C).

Warning

Do not call the buffer reading routine directly. Its entry address will not be the same in future versions of the computer.

The special characters (CONTROL)-(S) (stop list) and (CONTROL)-(C) (stop Applesoft execution) do not work while keyboard buffering is turned on. A new keystroke, (*)-(CONTROL)-(X), clears the buffer.

Using Keyboard Buffering Firmware

See Chapter 8.

Keyboard buffering is automatically turned on when the serial firmware is placed in terminal mode. Otherwise you must turn it on yourself.

- 1. Disable processor interrupts (SEI).
- Set location \$5FA to \$80. This tells the firmware to buffer keystrokes without calling the user's interrupt handler.
- Set locations \$5FF and \$6FF to \$80. These are pointers to where in the buffer the next keystroke will be stored and where the next will be read from, respectively.
- 4. Turn on the ACIA for port 2 by setting the low nibble of \$C0AA to the value \$F. For example:

LDA \$COAA ;read port 2 ACIA command register

DRA #\$0F ;set low nibble to \$F

STA \$COAA ;set port 2 ACIA command register

If you are using the serial ports at the same time, just set the low bit of \$C0AA to 1. This prevents receiver interrupts from being turned off.

A PR#2 or IN#2 or the equivalent will shut off keyboard interrupts.

5. Enable processor interrupts (CLI).

Using Keyboard Interrupts Through Firmware

Keyboard interrupts are received through the ACIA for port 2. They can be enabled as follows:

- 1. Disable processor interrupts (SEI).
- 2. Set location \$5FA to \$C0. This tells the firmware to identify a keystroke interrupt, and to call the user's interrupt handler.
- 3. Turn on the ACIA for port 2 by setting the low nibble of \$C0AA to the value \$F. For example:

LDA \$COAA

;read port 2 ACIA command register

ORA #\$0F

;set low nibble to \$F

STA \$COAA

;set port 2 ACIA command register

4. Enable processor interrupts (CLI).

When the user's interrupt handler is called, it can identify the keyboard as the interrupt source by reading location \$4FA. This is a copy of the ACIA status register at the time of the interrupt. If the interrupt was due to something on the ACIA for port 2, bit 7 is set. If the interrupt was caused by a keystroke, bit 6 is set and bit 5 is unchanged.

After servicing this interrupt, the interrupt handler should clear the interrupt by setting \$4FA to 0.

E.6.3 Using External Interrupts Through Firmware

Pin 9 of the external disk drive connector (EXTINT) can be used to generate interrupts through the ACIA for port 1. It can be used as a source of interrupts (on a high-to-low transition) if enabled as follows:

- 1. Disable processor interrupts (SEI).
- Set location \$5F9 to \$C0. This tells the firmware to identify an external interrupt, and to call the user's interrupt handler.
- Turn on the ACIA for port 1 by setting the low nibble of \$C09A to the value \$F. For example:

LDA \$C09A

;read port 1 ACIA command register

ORA #\$0F

;set low nibble to \$F

STA \$C09A

;set port 1 ACIA command register

4. Enable processor interrupts (CLI).

When the user's interrupt handler is called, it can identify this interrupt by reading location \$4F9. This is a copy of the ACIA status register at the time of the interrupt. If the interrupt was due to something on the ACIA for port 1, bit 7 is set. If the interrupt was caused by the external interrupt line, bit 6 is clear and bit 5 is unchanged.

After servicing this interrupt, the interrupt handler should clear the interrupt by setting \$4F9 to 0.

E.6.4 Firmware for Serial Interrupts

The Apple IIc hardware is able to generate interrupts both when the ACIA receives data and when it is ready to send data. The built-in interrupt handler responds to incoming data only. The firmware is able to buffer up to 128 incoming bytes of serial data from either serial port. After the buffer is full, data is ignored. Only one port can be buffered at a time.

The following sections assume that the serial port to be buffered is already initialized, as explained in Chapter 8.

Using Serial Buffering Transparently

Serial buffering is automatically turned on when the serial firmware is placed in terminal mode. Otherwise you must turn it on yourself, as follows:

- 1. Disable processor interrupts (SEI).
- Set location \$4FF to \$C1 to buffer port 1, or to \$C2 to buffer port 2.
- 3. Set locations \$57F and \$67F to 0. These are pointers to the next byte in the buffer to be used and the next character to be read from the buffer, respectively.
- 4. Turn on the ACIA for the port by setting the low nibble of \$C09A for port 1 or \$C0AA for port 2 to \$D. For example:

LDA \$C09A ;read port 1 ACIA command register
AND \$F0 ;clear low nibble

DRA #\$0D ;set low nibble to \$D

STA \$C09A ;set port 1 ACIA command register

The 0 in bit 1 of the command register enables receiver interrupts, thus an interrupt is generated when a byte of data is received.

5. Enable processor interrupts (CLI).

When serial port buffering is thus enabled, normal reads from the serial port firmware fetch data from the buffer rather than directly from the ACIA.

See Chapter 8.

Using Serial Interrupts Through Firmware

It is also possible to use the firmware to call the user interrupt handler whenever a byte of data is read by the ACIA. In this mode buffering is not performed by the firmware.

- 1. Disable processor interrupts (SEI).
- 2. Set location \$4FF to a value other than \$C1 or \$C2.
- 3. Turn on the ACIA for the port by setting the low nibble of \$C09A for port 1 or \$C0AA for port 2 to \$D. For example:

LDA \$C09A ;read port 1 ACIA command register
AND \$F0 ;clear low nibble

DRA #\$0D ;set low nibble to \$D

STA \$C09A ;set port 1 ACIA command register

The 0 in bit 1 of the command register enables receiver interrupts, thus an interrupt is generated when a byte of data is received.

4. Enable processor interrupts (CLI).

When a serial port is thus enabled, the user's interrupt handler is called each time the port receives a byte of data. The status byte saved by the firmware (\$4F9 for port 1; \$4FA for port 2) has the high bit set if the interrupt occurred on that port. Bit 3 is set if the interrupt was due to a received byte of data.

The interrupt handler should clear the interrupt by clearing bits 7 and 3 of that port's status byte (\$4F9 for port 1; \$4FA for port 2).

Transmitting Serial Data

The serial firmware does not implement buffering for serial output. Instead it waits for two conditions to be true before transmitting a character:

- The ACIA's transmit register must be ready to accept a character. This is true if bit 4 of the ACIA's status register is 1.
- The device must signal that it is ready to accept data. This is true if bit 5 of the ACIA's status register is 0. Bit 5 is 0 if pin 5 of the port's connector is also 0.

When the serial firmware is active, a change of state on pin 5 of that port generates an interrupt. That interrupt is absorbed, but the data remains in bit 5 of the status register. Interrupts from the ACIA's transmit register are normally disabled.

A Loophole in the Firmware

So that programs can make use of interrupts on the ACIAs without affecting mouse interrupt handling, there is a tiny loophole purposely left in the built-in interrupt handler. If transmit interrupts are enabled on the ACIA—that is, if bits 3, 2, and 0 of the ACIA's command register have the values 0, 1, and 1, respectively—then control is passed to the user's interrupt handler if the interrupt is not intended for the mouse (movement, button, or VBL).

This means that you can write more sophisticated serial interrupt handling routines than the limited firmware space could provide (such as printer spooling). The firmware will still set memory to its standard state, handle mouse interrupts, and restore memory after your routine is finished.

When you receive the interrupt, neither ACIA's status register has been read. You are fully responsible for checking for interrupts on both ACIAs, determining which of the four interrupt sources on each ACIA caused the interrupt, and how to handle them. Refer to the 6551 specification for more details. The built-in firmware itself is an excellent example of how interrupts on the ACIA can be handled.

E.7 Bypassing the Interrupt Firmware

The following sections give further details on using interrupts on the Apple IIc computer without using the built-in interrupt handler.

E.7.1 Using Mouse Interrupts Without the Firmware

To use mouse interrupts without the firmware, as mentioned above, you must set your own interrupt vectors. If \$D000-\$FFFF ROM is ever switched in, the built-in interrupt handler will absorb the mouse interrupts. Tables E-1 and E-2 show how to activate and read mouse interrupts without using the firmware. Remember to disable interrupts (SEI) before enabling mouse interrupts, then turn them on when done (CLI).

Table E-1. Activating Mouse Interrupts

To Activate Interrupts On	Enable IOU Access	Select Source	Enable Source	Disable IOU Access
Mouse X (rising edge)	STA \$C079	STA \$C05C	STA \$C059	STA \$C078
Mouse X (falling edge)	STA \$C079	STA \$C05D	STA \$C059	STA \$C078
Mouse Y (rising edge)	STA \$C079	STA \$C05E	STA \$C059	STA \$C078
Mouse Y (falling edge)	STA \$C079	STA \$C05F	STA \$C059	STA \$C078
VBL	STA \$C079		STA \$C05B	STA \$C078

Table E-2. Reading Mouse Interrupts

To Read Interrupts From	Read Direction (A.S.A.P.)	Determine Source	Handle It	Return
Mouse X	LDA \$C066	LDA \$C015 (bit 7=1 if true)	Six	RTI
Mouse Y	LDA \$C067	LDA \$C017 (bit 7=1 if true)		RTI
VBL		LDA \$C019 (bit 7=1 if true)	1110	RTI

The mouse direction data read from \$C066 and \$C067 is guaranteed to be valid for at least 40 microseconds. Average duration is at least 200 microseconds. This means you should read the direction as soon as possible.

E.7.2 Using ACIA Interrupts Without the Firmware

To use ACIA interrupts without the firmware, you must set your own interrupt vectors. If the \$D000-\$FFFF ROM is ever switched in, the built-in interrupt handler will handle the interrupt as determined by certain mode bytes (section E.6.1).

When writing your serial interrupt handler, refer to Figures 11.31 through 11-33 and to the Synertek 6551 ACIA specification. As shown in Chapter 11, the ACIA's have the following connections:

Port 1:

DSR line connected to the EXTINT line on

the external disk port

DCD line connected to pin 5 of Port 1

connector

Port 2:

DSR line goes high when a key is

pressed

DCD line connected to pin 5 of Port 2

connector

The ACIA registers have the following addresses:

Port 1: Data Register

= \$C098

Status Register Command Register \$C099

Control Register

\$C09A \$C09B

Port 2: Data Register

Status Register

= \$C0A8 = \$C0A9

Command Register

\$COAA

Control Register

\$COAB

Apple II Series Differences

This appendix compares the Apple IIc to the Apple IIe, Apple II Plus, and Apple II.

F.1 Overview

This appendix does not contain an exhaustive list of differences. However, it does include those differences most likely to affect the accuracy of programs, displays, and instructions created for end users of two or more models from the Apple II Series.

As an overview, the differences between the Apple II series computers can be expressed as a series of equations: this computer equals that one plus or minus certain features.

Note: The following *equations* are merely an overview of what each model of Apple II Series is with respect to its predecessor. These equations are in terms of functional equivalence, not strict equality. For example,

Apple IIe = Apple II Plus + Apple Language Card

does not mean there is an actual language card or slot—just that the one machine functions as if it were the other with such a card (with its connector) in a slot.

Apple II Plus = II + Autostart ROM Applesoft firmware + 48K RAM standard Old Monitor ROM Integer BASIC firmware Apple IIe II Plus Apple Language Card (with 16K of RAM) 80-column (enhanced) video firmware + built-in diagnostics + full ASCII keyboard + internal power light + FCC approval + improved back panel + 9-pin back panel game connector + auxiliary slot (with possibility of 80-column text card + extra 64K RAM) slot 0 Apple IIc lle + extended 80-column text card 80/40 switch + keyboard switch + disk light + disk controller port + disk drive + mouse port + serial printer port + serial communication port

removable coverslots 1 to 7auxiliary slot

+ built-in port firmware

- internal power light - cassette I/O connectors

internal game I/O connector (hence no game *output*)

video expansion connector

- auxiliary video pin

monitor cassette support

F.1.1 Type of CPU

The CPU in the Apple II and II Plus is the 6502. The Apple IIe uses a 6502A. The Apple IIc uses the 65C02: this is a redesigned CMOS CPU that has 27 new instructions, new addressing modes, and for some instructions a differing execution scheme and machine cycle counts (see Appendix A). Programs written for the Apple IIc will run on the earlier machines only if they do not contain instructions unique to the 65C02, or depend on instruction cycle times that differ.

F.1.2 Machine Identification

Identification of Apple II series computers is as follows:

Machine	\$FBB3	\$FBC0	\$FB1E
Apple II	\$38		
Apple II Plus	\$EA		
Apple IIe	\$06	SEA	
Apple IIc	\$06	\$00	
Apple III in Apple II			
Emulation Mode	\$EA		\$8A

Any future Apple II series computer or ROM release will have different values in these locations. Machine identification routines are available from Apple Vendor Technical Support.

With regard to ProDOS, its MACHID byte, at location \$BF98 on the global page, will have bit 3 set to 0 if the computer is an Apple II, II Plus, IIe, or III, and a 1 if the computer is not one of these machines. In addition, for an Apple IIc, bits 7 and 6 are set to binary 10.

Bits 7 and 6 set to binary 10 indicate that a computer is Apple IIe and IIc compatible, regardless of the value of bit 3.

F.2 Memory Structure

This section compares the memory organization of the Apple IIc with that of the Apple II, II Plus, and IIe. These machines differ in RAM space, ROM space, slot or port address space, and hardware page use.

F.2.1 Amount and Address Ranges of RAM

The Apple II could have as little as 4K of RAM at the time of purchase, and could be upgraded to as much as 48K of RAM, following a procedure described in the *Apple II Reference Manual*.

The Apple II Plus has 48K of RAM (\$0000 through \$BFFF) as a standard feature. With the addition of an Apple Language Card, a 48K Apple II or II Plus could be expanded to have 64K of RAM.

The Apple IIe has a full 64K of RAM. The top 12K addresses overlap with the ROM addresses \$D000 through \$FFFF. There is an additional bank-switched area of 4K from \$D000 through \$DFFF. This arrangement is equivalent to an Apple II Plus with an Apple Language Card installed. A program selects between the RAM and ROM address spaces and between the \$Dxxx banks by changing soft switches located in memory.

With an Extended 80-Column Text Card installed in its auxiliary slot, an Apple Ile has an additional 64K of RAM available, although no more than half of the 128K of RAM space is available at any given time. Soft switches located in memory control these address space selections.

The RAM in the Apple IIc is equivalent to the RAM in an Apple IIe with an Extended 80-column Card.

F.2.2 Amount and Address Ranges of ROM

The Apple II has 8K of ROM (\$E000 through \$FFFF), and the Apple II Plus has 12K of ROM (\$D000 through \$FFFF). Users can plug their own ROMs into the sockets provided. The on-board (as opposed to slot) ROM address range is from \$D000 through \$FFFF.

The Apple IIe has 16K of ROM, of which it uses 15.75 K (addresses \$C100 through \$FFFF; page \$C0 addresses are for I/O hardware). ROM addresses \$C300 through \$C3FF (normally assigned to the ROM in a card in slot 3) and \$C800 through \$CFFF contain 80-column video firmware; ROM addresses \$C100 through \$C2FF and \$C400 through \$C7FF (normally assigned to the ROM on cards in slots 1, 2, 4, 5, 6 and 7) contain built-in self-test routines.

A soft switch in RAM controls whether the video firmware or slot 3 card ROM is active. Invoking the self-tests with

(*)-(CONTROL)-(RESET) causes the self-test firmware to take over the slot ROM address spaces.

The Apple IIc ROM also uses the 15.75 K from \$C100 through \$FFFF, and its enhanced video firmware has the same entry point addresses as on the Apple IIe. However, there are only rudimentary built-in self-tests, and these do not pre-empt any port firmware space.

In the Apple IIc, addresses \$C100 through \$CFFF contain I/O and interrupt firmware, addresses \$D000 through \$F7FF contain the Applesoft BASIC Interpreter, and addresses \$F800 through \$FFFF contain the Monitor.

F.2.3 Peripheral-Card Memory Spaces

Each Apple IIc port has up to sixteen peripheral-card I/O space locations in main memory on the hardware page (beginning at location C0s0 + 80 for slot or port s), allocated in the standard Apple II series way (that is, beginning at location C0s0 + 80 for each slot s).

The peripheral-card ROM space (page \$Cs for slot s in the Apple II, II Plus, and IIe) contains the starting and entry-point addresses for port s, but port routines are not limited to their allocated \$Cs pages.

The 2K-byte expansion ROM space from \$C800 to \$CFFF in the Apple IIc is used by the enhanced video firmware and miscellaneous I/O and memory-transfer routines.

The 128 bytes of peripheral-card RAM space or *scratch-pad RAM* (64 screen holes in main memory and their equivalent addresses in auxiliary memory) are reserved for use by the built-in firmware. It is extremely important for the correct operation of Apple IIc firmware that these locations not be altered by software except for the specific purposes described in Chapters 7, 8, and 9, and in Appendix E.

F.2.4 Hardware Addresses

The hardware page (the addresses from \$C000 through \$C0FF) controls memory selection and input/output hardware characteristics. All input and output (except video output) takes place at one or more hardware page addresses. For the sake of simplicity, this section presents only a general comparison between the Apple IIc on the one hand, and the Apple II, II Plus, and IIe on the other, with respect to most hardware page uses. However, for many characteristics, the Apple IIe and IIc work one way, while the Apple II and II Plus work another.

\$C000 to \$C00F

On all Apple II series computers, reading any one of these addresses reads the keyboard data and strobe. On the Apple IIe and IIc, writing to each of these addresses turns memory and display switches on and off. Writing to addresses \$C006, \$C007, \$C00A, and \$C00B performs ROM selection on the Apple IIe. Writing to these four addresses is reserved on the Apple IIc.

For reading the keyboard, use \$C000; reserve \$C001 through \$C00F.

\$C010 to \$C01F

On all Apple II series computers, writing to any one of these addresses clears the keyboard strobe. On the Apple IIe and IIc, reading each of these addresses checks the status of a memory or display switch, or the any-key-down flag.

For clearing the keyboard strobe, use \$C010; reserve \$C011 through \$C01F.

Reading \$C015 checks the SLOTCXROM switch on the Apple IIe, but it resets the X-movement interrupt (XINT) on the Apple IIc. Similarly, reading \$C017 checks the SLOTC3ROM switch on the Apple IIe, but it resets the Y-movement interrupt (YINT) on the Apple IIc.

Reading \$C019 checks the current state of vertical blanking (VBL) on the Apple IIe, but it resets the latched vertical blanking interrupt (VBLINT) on the Apple IIc.

\$C020 to \$C02F

On the Apple II, II Plus, and IIe, reading any address \$C02x toggles the cassette output signal. On the Apple IIc, both reading from and writing to these locations are reserved.

\$C030 to \$C03F

On all Apple II series computers, reading an address of the form \$C03x toggles the speaker. For full Apple II series compatibility, toggle the speaker using \$C030, and reserve \$C031 through \$C03F.

On the Apple IIc, writing to these addresses is explicitly reserved.

\$C040 to \$C04F

On the Apple II, II Plus, and IIe, reading any address of the form \$C04x triggers the Utility Strobe. The Apple IIc has no Utility Strobe.

On the Apple IIc, addresses \$C044 through \$C047 are explicitly reserved, and reading or writing any address from \$C048 through \$C04F resets both the X and Y interrupts (XINT and YINT).

\$C050 to \$C05F

Addresses \$C050 through \$C057 work the same on the Apple IIc as on the Apple IIe: they turn the TEXT, MIXED, PAGE2 and HIRES switches on and off.

On the Apple IIe, addresses \$C058 through \$C05F turn the annunciator outputs on and off. On an Apple IIe with a revision B main logic board, an Apple Extended 80-Column Text Card, and a jumper installed on the card, reading locations \$C05E and \$C05F set and clear double-high-resolution display mode.

On the Apple IIc, if the IOUDIS switch is on, both reading from and writing to addresses \$C058 through \$C05D are reserved, and addresses \$C05E and \$C05F set and clear double-high-resolution display (as on the Apple IIe equipped as described in the preceding paragraph). If the IOUDIS switch is off, then addresses \$C058 through \$C05F control various characteristics of mouse and vertical blanking interrupts (Table 9-2).

\$C060 to \$C06F

On the Apple IIc, writing to any address of the form \$C06x is reserved, and reading addresses \$C068 through \$C06F is reserved.

Reading addresses \$C061 and \$C062 is the same as on the Apple IIe (switch inputs and Apple keys). Reading addresses \$C064 and \$C065 is the same as on all other Apple II series computers (analog inputs 0 and 1).

On the Apple IIc, address \$C063 bit 7 is 1 if the mouse switch is not pressed, and 0 if it is pressed, so that software looking for the *shift-key mod* (used on Apple II, II Plus, and IIe with some text cards) will *find* it and display lowercase correctly. If by chance the mouse button is pressed when the software checks location \$C063, it will appear that the shift-key mod is not present.

On the Apple IIc, address \$C060 is used for reading the state of the 80/40 switch; on the Apple II, II Plus, and IIe, this address is for reading cassette input.

The Apple IIc has two, rather than four, analog (paddle) inputs. Addresses \$C066 and \$C067 are used for reading the mouse X and Y direction bits.

\$C070 to \$C07F

On the Apple II, II Plus, and IIe, reading from or writing to any address of the form \$C07x triggered the (analog input) paddle timers.

On the Apple IIc, only address \$C070 is to be used for that one function. Addresses \$C071 through \$C07D are explicitly reserved. The results of reading from or writing to addresses \$C07E and \$C07F are described in Table 5-8.

\$C080 to \$C08F

On the Apple IIe and IIc, accessing addresses in this range selects different combinations of bank-switched memory banks. However, addresses \$C084 through \$C087 duplicate the functions of the four addresses preceding them, and addresses \$C08C through \$C08F do also. These eight addresses are explicitly reserved on the Apple IIc.

\$C090 to \$C0FF

On the Apple II, II Plus, and IIe, each group of 16 addresses of the form C080 + s0 is allocated to an interface card (if present) in slot s.

On the Apple IIc, addresses corresponding to slots 1, 2, 3, 4 and 6 are allocated to a serial interface card, communication interface card, 80-column text card, mouse interface card, and disk controller card, respectively. All other addresses in this range are reserved.

F.2.5 Monitors

The older models of the Apple II and Apple II Plus included a different version of the System Monitor from the one built into more recent models (and the Apple IIe and IIc). The older version, called the Monitor ROM, had the same standard I/O subroutines as the newer Autostart ROM, but a few of their features were different; for example, there were no arrow keys for vertical cursor motion.

When you start the Apple IIc with a DOS or BASICS disk and it loads Integer BASIC into the bank-switched area in RAM, it loads the old Monitor along with it. When you type INT from Applesoft to activate Integer BASIC, you also activate this copy of the old Monitor, which remains active until you either type FP to switch back to Applesoft, which uses the new Monitor in ROM, or activate the 80-column firmware.

F.3 I/O in General

Apple IIc I/O is different from I/O on the Apple II, II Plus, and IIe in three important respects: the possibility of direct memory access (DMA) transfers, the presence or absence of slots, and the presence or absence of built-in interrupt handling.

F.3.1 DMA Transfers

The Apple II, II Plus, and IIe allow DMA transfers, because both the address and the data bus are available at the slots. No true DMA transfer is possible with the Apple IIc because neither bus is available at any of the back-panel connectors.

F.3.2 Slots Versus Ports

The Apple II and II Plus have eight identical slots; the Apple IIe has seven identical slots plus a 60-pin auxiliary slot for video, add-on memory and test cards. The Apple IIc has no slots; instead, it has built-in hardware and firmware that are functional equivalents of slots with cards in them (and back-panel connectors). These are called **ports** on the Apple IIc.

F.3.3 Interrupts

Interrupts on the Apple IIc are described in Appendix E.

The Apple IIc is the first computer in the Apple II Series to have built-in interrupt-handling capabilities.

F.4 Keyboard

Both keyboard layout and character sets vary in the Apple II series computers. The major keyboard difference in the Apple II Series is that the Apple IIe and IIc have full ASCII keyboards, while the Apple II and II Plus do not.

F.4.1 Keys

The Apple II and II Plus have identical 52-key keyboards. The Apple IIe and Apple IIc keyboards have the same 63-key full ASCII keyboard layout, with new and repositioned keys and characters as compared to the Apple II and II Plus. While the Apple II and II Plus have a REPT key, the IIe and IIc have an auto-repeat feature built into each character key.

Some Apple II and Apple II Plus machines have a slide switch inside the case, under the keyboard edge of the cover, for selecting whether or not (RESET) works without (CONTROL). On the Apple IIe and Apple IIc, there is no choice: (CONTROL)-(RESET) works, and (RESET) alone does not.

The Apple IIc and IIe have an (a) and a (b) key; the Apple II and II Plus do not have these two keys.

The captions on several keys—(ESC), (TAB), (CONTROL), (SHIFT), (CAPS-LOCK), (DELETE), (RETURN), and (RESET)—can vary: on the Apple II and II Plus some are abbreviated or missing; on the Apple IIc all keycaps are lowercase italic; on international models, some captions are replaced by symbols (Appendix G).

The Apple IIc has two switches that the other models do not have. One switch is for changing between 40-column and 80-column display, the other is for selecting keyboard layout (Sholes versus Dvorak on USA models), or both keyboard layout and character set (on international models).

The position of the power-on light differs on the Apple II and II Plus, Apple IIe, and Apple IIc. The Apple IIc has a disk-use light as well.

F.4.2 Character Sets

The Apple II and II Plus keyboard character sets are the same. They are described in the *Apple II Reference Manual*.

The Apple IIe and Apple IIc keyboard character sets are the same: full ASCII. The standard (Sholes) layout and key assignments are described in the *Apple IIe Reference Manual*. The Dvorak layout and key assignments are described in Chapter 4 and Appendix G of this manual.

To change between the two available keyboard layouts requires modification to the main logic board on the Apple IIe, but only toggling of the keyboard switch on the Apple IIc.

Apple Computer, Inc. manufactures fully localized models (power supply and character sets) of both the Apple IIe and the Apple IIc. However, there are minor variations in keyboard layout, even among early and late productions models of the same machine. For further details, refer to Appendix G of this manual or to the Apple IIe Supplement to the Owner's Manual.

F.5 Speaker

The Apple IIc has two speaker features that the three previous models do not have. They are a two-channel, but monaural, mini-phone jack for headphones—which disconnects the internal speaker when something is plugged into it—and a volume control.

F.6 Video Display

This section discusses the general differences between Apple IIc video display capabilities and those of the other computers in the series. Note however that as new ROMs become available for the Apple IIe, many differences between these two machines will vanish.

F.6.1 Character Sets

The Apple II and II Plus display only uppercase characters, but they display them in three ways: normal, inverse, and flashing. The Apple IIc and IIe can display uppercase characters in all three ways, and they can display lowercase characters in the normal way. This combination is called the **primary character**

The Apple IIc and IIe have another character set, called the alternate character set, that displays a full set of normal and inverse uppercase and lowercase characters, but can't display flashing characters. The primary and alternate character sets are described in Chapter 5. You can switch character sets at any time by means of the ALTCHAR soft switch, also described in Chapter 5.

Flashing display must not be used with the enhanced video firmware active. Use it in 40-column mode with the enhanced video firmware turned off; otherwise, strange displays may result, such as MouseText characters appearing in place of uppercase letters.

To be compatible with some software, you have to switch the Apple IIc keyboard to uppercase by pressing CAPS LOCK).

F.6.2 MouseText

MouseText characters (Chapter 5) are available on every Apple IIc, and on any Apple IIe that has had its ROMs appropriately upgraded, if necessary.

F.6.3 Vertical Blanking

A signal called **vertical blanking** indicates when a display device should stop projecting dots until the display mechanism returns from the bottom of the screen to the top to make another pass. During this interval, a program can make changes to display memory pages, and thus provide a smooth, flicker-free transition to a new display.

On the Apple IIe, vertical blanking (VBL) is a signal whose level must be polled. (VBL is not available to software on the Apple II or II Plus.) On the Apple IIc, vertical blanking is an interrupt (VBLINT) that occurs on the trailing edge of the active-low VBL signal. Programs intended to run on all Apple II series computers must take this difference into account.

F.6.4 Display Modes

All models have 40-column text mode, low-resolution graphics mode, high-resolution graphics mode, and mixed graphics and text modes. The Apple IIe (revision B motherboard) with an Apple Extended 80-Column Text Card, and the Apple IIc have double-high-resolution graphics mode also.

F.7 Disk I/O

The Apple II, II Plus, and IIe can support up to six (four is the recommended maximum) disk drives attached in controller cards plugged into slots 6, 5, and 4. The Apple IIc supports up to two disk drives: its built-in drive (treated as slot 6 drive 1), and one external disk drive (treated as slot 6 drive 2; also treated as slot 7 drive 1 under ProDOS) for external-drive startup purposes.

F.8 Serial I/O

The Apple IIc serial ports (ports 1 and 2) are similar to Super Serial Cards installed in slots 1 and 2 of an Apple IIe. The serial port commands are a slightly modified subset of Super Serial Card commands. This subset includes all the commands supported by the earlier Apple Serial Interface Card and Communication Card.

F.8.1 Serial Ports Versus Serial Cards

There are several important differences between Apple IIc serial ports and other Apple II series computers with serial cards installed in them.

Apple IIc serial ports have no switches. Instead, initial values are moved from firmware locations into auxiliary memory when the power is turned on. Changes made to these values in auxiliary memory remain in effect until the power is turned off. Pressing (a)-(CONTROL)-(RESET) does not change them.

When the port itself is turned on (with an IN or PR command), the initial values in auxiliary memory are placed in the main memory screen holes assigned to the port. These characteristics can be changed by the port commands. The changed characteristics remain in effect until the port is turned off and then on again (with PR and IN commands).

F.8 Serial I/O

The command syntax for the Apple IIc ports also differs from the syntax for serial cards. A separate command character, (CONTROL)-(A) or (CONTROL)-(I), must precede each individual port command, whereas several commands to a serial card can be strung together between the command character and a carriage return character.

The letters used for some of the commands have been changed from those used with the Super Serial Card (such as S instead of B for sending a BREAK signal). Each serial port command letter is unique to simplify command interpretation.

Changing the command character from CONTROL-A to CONTROL-I, or vice versa, makes the Super Serial Card change from communication mode to printer mode and back; this is not the case with Apple IIc serial ports. With the Apple IIc, use the System Utilities Disk to change modes.

Super Serial Card commands support several functions that Apple IIc serial port commands don't support: masking incoming line feed after carriage return; translating incoming characters, such as changing lowercase to uppercase (for the benefit of the Apple II or II Plus); delaying after sending carriage return, line feed, or form feed; ignoring keyboard input, and so on.

Following a CONTROL-I nnnN command, the Apple IIc automatically generates carriage return after nnn characters; with the Super Serial Card, you need to turn this on with CONTROL-I C.

F.8.2 Serial I/O Buffers

The communication port firmware uses auxiliary memory page 8 as an input and output buffer. By doing so, the firmware can keep up with higher baud rates. It can also *hide* data from the Monitor, Applesoft, and other system software.

Programs written for the Apple IIe or IIc can, of course, store information in auxiliary memory page 8. However, such information will be destroyed when the communication port is activated.

F.9 Mouse and Hand Controls

The DB-9 back-panel connector on the Apple IIc is used for both the mouse and hand controls. On the Apple IIc, the DB-9 connector supports hand controls only. On the Apple IIe, the mouse must use the connector on the interface card.

F.9.1 Mouse Input

The Apple IIc provides built-in firmware support for a mouse connected to the DB-9 mouse and hand control connector. Apple IIc mouse support includes mouse movement and button interrupts (and vertical blanking interrupts for synchronization with the display); Apple IIe mouse support relies on polling VBL instead of vertical blanking interrupts.

As a result of how interrupts are handled on the two machines, the mouse firmware routine calls function somewhat differently for the Apple IIc and Apple IIe. However, using the calls in the manner described in Chapter 9 ensures mouse support compatibility between the two machines.

The ratio of mouse movement to cursor movement is different on the Apple IIc than it is on the Apple IIe.

F.9.2 Hand Control Input and Output

The Apple II, II Plus, and IIe have a 16-pin game I/O connector inside the case that supports three switch inputs, four analog (paddle) inputs, and four annunciator outputs. The Apple IIe and Apple IIc have a DB-9 back-panel connector that supports the three switch inputs and two paddle inputs (plus two more on the internal GAME I/O connector of the Apple II, II Plus, and IIe).

The Apple IIc does not support the four annunciator outputs.

The voltage-current curve for hand controls differs for the Apple IIc compared with that of the Apple II, II Plus, and IIe. Compare Figure F-1 with Figure 11-42. This was done so the hardware would support identifiable mouse and hand control signals using the same circuits.

Figure F-1. Apple II, II Plus, and IIe Hand Control Signals

The paddle timing circuit on the Apple II Plus is slightly different than the one on the Apple IIe and IIc. On the Apple IIe and IIc the 100 ohm fixed resistor is betwen the NE556 discharge lead and the capacitor; the variable resistor in the paddle is connected directly to the capacitor. On the Apple II Plus, the capacitor is conected directly to the discharge lead, and the fixed resistor is in series with the paddle resistor.

F.10 Cassette I/O

The Apple II, II Plus, and IIe all have cassette input and output jacks, memory locations, and monitor support. The Apple IIc does not.

F.11 Hardware

Besides the different microprocessors used in various models in the Apple II series (section F.1.1), there are important differences in power specifications and custom chips.

F.11.1 Power

The power supplies for the Apple II, II Plus, and IIe are essentially the same. The floor transformer and voltage converter for the Apple IIc have smaller capacity for current and heat dissipation. Therefore, it is important to observe the load limits specified in each of the reference manuals.

F.11.2 Custom Chips

The Apple IIe custom chips (Memory Management Unit and Input/Output Unit) replaced dozens of Apple II Plus chips, and added the functionality of dozens more. The Apple IIc has custom MMU and IOU chips, too, but they represent different bonding options, and so their pin assignments are not compatible.

In addition, the Apple IIc has a custom General Logic Unit (GLU), Timing Generator (TMG), and Disk Controller Unit (IWM). The Apple IIc has two hybrid units (AUD and VID) for audio and video amplification.

USA and International Models

This appendix repeats some of the keyboard information given in Chapter 4 for the two USA keyboard layouts for easy comparison with the other layouts available. Following these there is a composite table of the ASCII codes and the characters associated with them on all the models discussed.

G.1 Keyboard Layouts and Codes

Each of the following subsections has a keyboard illustration and a table of the codes that result from the possible keystrokes. Note, however, that Table G-1 is the basic table of keystrokes and their codes. For simplicity, subsequent tables (up to Table G-6) list only the keystrokes and codes that differ from those in Table G-1.

For example, pressing the (A) key produces *a* (hexadecimal 61); pressing (SHIFT)-(A) produces uppercase *A* (hexadecimal 41); pressing (CONTROL)-(A) or (CONTROL)-(SHIFT)-(A) produces *SOH* (the ASCII Start Of Header control character, hexadecimal 01). You can tell that this key has the same effect on all keyboards, from the fact that nothing appears in Tables G-2 through G-7 for that key.

A quick way to find out which characters in the ASCII set change on international keyboards is to check Table G-7. In fact, only a few of them change. The pairing of characters on keys varies more.

Note: On all but the French and Italian keyboards, CAPS-LOCK affects only keys that can produce both lowercase letters (with or without an accent) and their uppercase equivalents. With these keys, CAPS-LOCK down is equivalent to holding down (SHIFT), resulting in uppercase instead of lowercase. If a key produces only a lowercase version of an accented letter, then CAPS-LOCK) does not affect it.

On the French and Italian keyboards, (CAPS-LOCK) shifts all the keys. Furthermore, on the French keyboard, when (CAPS-LOCK) is down, the (SHIFT) key undoes the shifting.

Note: The shapes and arrangement of keys in Figures G-1 and G-2 follow the ANSI (American National Standards Institute) standard, which is used mainly in North and South America. The shapes and arrangement of keys in Figure G-3 follows the ISO (International Standards Organization) standard used in Europe and elsewhere.

The only differences between the ANSI and ISO versions of the USA keyboard are

- The shapes of three keys: the left SHIFT key, CAPS-LOCK, and (RETURN).
- The resulting repositioning of two keys (and) in Figures G-1 and G-3.
- For some countries, there are arrow symbols on TAB, (CAPS-LOCK), (RETURN), and the two (SHIFT) keys (as shown in Figure G-3).

G.1.1 USA Standard (Sholes) Keyboard

Figure G-1 shows the Standard (Sholes) keyboard as it is laid out for USA models of the Apple IIc with the keyboard switch up. Table G-1 lists the ASCII codes resulting from all simple and combination keystrokes on this keyboard.

Figure G-1. USA Standard or Sholes Keyboard (Keyboard Switch Up)

Table G-1. Keys and ASCII Codes. Codes are shown here in hexadecimal; to find the decimal equivalents, use Table G-7.

Key	Key Alone Hex	Char	CONTROL Hex	+ Key Char	SHIFT + Hex	Key Char	Both + Hex	Key Char

G.1.2 USA Simplified (Dvorak) Keyboard

Figure G-2 shows the Dvorak layout of the USA keyboard. Characters are paired up on keys in exactly the same way as on the USA Standard keyboard; only individual key positions are changed. In fact, you can change the keycap arrangement to match Figure G-2, lock the keyboard switch in its down position, and have a working Dvorak keyboard. All keystrokes produce the same ASCII codes as those shown in Table G-1.

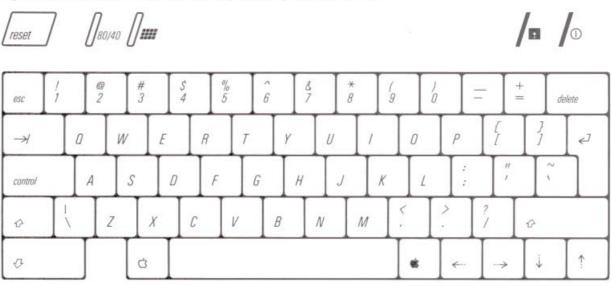

Figure G.2. USA Simplified or Dvorak Keyboard (Keyboard Switch Down)

G.1.3 ISO Layout of USA Keyboard

Figure G-3 shows the layout of the keyboard of all ISO European keyboards (except the Italian keyboard) when the keyboard switch is up. All keystrokes produce the same ASCII codes as those shown in Table G-1.

Figure G-3. ISO Version of USA Standard Keyboard (Keyboard Switch Up)

G.1.4 English Keyboard

With the keyboard switch up, the English model of the Apple IIc keyboard layout is as shown in Figure G-3, and keystrokes produce the ASCII codes shown in Table G-1.

With the keyboard switch down, the English model keyboard layout is as shown in Figure G-4. The change in ASCII code production (from that in Table G-1) is shown in Table G-2.

The only changed character is the substitution of the British pound-sterling symbol (\mathfrak{L}) for the cross-hatch symbol (#) on the shifted 3-key.

Figure G-4. English Keyboard (Keyboard Switch Down)

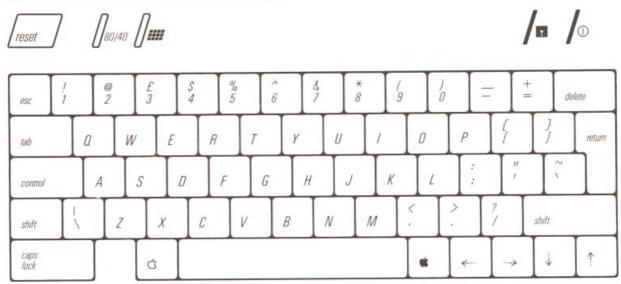

Table G-2. English Keyboard Code Differences From Table G-1

1221		Key Alone		CONTROL + Key		SHIFT + Key		Both + Key Hex Char	
Key	Hex	Char	Hex	Char	Hex	Char	пех	Cital	
3£	33	3	33	3	23	£	23	#	

G.1.5 French and Canadian Keyboards

With the keyboard switch up, the French model of the Apple IIc keyboard layout is as shown in Figure G-3, and the Canadian is as shown in Figure G-1. On both models, keystrokes produce the ASCII codes shown in Table G-1.

Note: On the French keyboard, CAPS-LOCK shifts to the upper characters on all keys. With CAPS-LOCK on, SHIFT "unshifts" to the lower character on any key pressed with it.

With the keyboard switch down, the French model keyboard layout is as shown in Figure G-5, and the Canadian model keyboard layout is as shown in Figure G-6. The changes in ASCII code production (from that in Table G-1) are shown in Table G-3.

Figure G-5. French Keyboard (Keyboard Switch Down)

G.1.6 German Keyboard

With the keyboard switch up, the German model of the Apple IIc keyboard layout is as shown in Figure G-3, and keystrokes produce the ASCII codes shown in Table G-1.

With the keyboard switch down, the German model keyboard layout is as shown in Figure G-7. The change in ASCII code production (from that in Table G-1) is shown in Table G-4.

Figure G-7. German Keyboard (Keyboard Switch Down)

G.1.7 Italian Keyboard

With the keyboard switch down, the Italian model keyboard layout is as shown in Figure G-8. The change in ASCII code production (from that in Table G-1) is shown in Table G-5.

With the keyboard switch up, the Italian model keyboard produces exactly the same ASCII codes for each key, but what is displayed differs for the ten characters shown in Table G-5 or Table G-7.

Figure G-8. Italian Keyboard (Keyboard Switch Down)

G.1.8 Western Spanish Keyboard

With the keyboard switch up, the Western (that is, American) Spanish model of the IIc keyboard layout is as shown in Figure G-1, and keystrokes produce the ASCII codes shown in Table G-1.

With the keyboard switch down, the Western Spanish model keyboard layout is as shown in Figure G-9. The change in ASCII code production (from that in Table G-1) is shown in Table G-6.

Figure G-9. Western Spanish Keyboard (Keyboard Switch Down)

Appendix G: USA and International Models

G.2 ASCII Character Sets

Table G-7 lists the ASCII (American National Standard Code for Information Interchange) codes that the Apple IIc uses, as well as the decimal and hexadecimal equivalents. Where there are differences between character sets, a circled number in the main table refers to a column in the lower part of the table.

Table G-7. ASCII Code Equivalents

G.3 Certifications

In the countries where they are applicable, these certifications replace the USA FCC Class B notice printed on the inside front cover of this manual. The safety instructions apply to all countries.

G.3.1 Radio Interference

This product is designed to comply with specification VDE 0871/6.78, Radio Frequency Interference Suppression of Radio Frequency Equipment, Level B.

G.3.2 Product Safety

This product is designed to meet the requirements of safety standard IEC 380, Safety of Electrically Energized Office Machines.

G.3.3 Important Safety Instructions

This equipment is intended to be electrically grounded. This product is equipped with a plug having a third (grounding) pin. This plug will fit only into a grounding-type alternating current outlet. This is a safety feature.

If you are unable to insert the plug into the outlet, contact a licensed electrician to replace the outlet and, if necessary, install a grounding conductor.

Do not defeat the purpose of the grounding-type plug.

G.4 Power Supply Specifications

The basic specifications of the power supply furnished with the Apple IIc for use in Europe and other countries having 50 Hz alternating current are shown in Table G-8.

Table G-8. 50 Hz Power Supply Specifications

Line voltage

199 to 255 VAC, 50 Hz

Maximum input

power consumption

25 W

Supply voltage

+15 V DC (nominal)

Supply current

1.2 A (nominal)

L

Conversion Tables

This appendix briefly discusses bits and bytes and what they can represent. It also contains conversion tables for hexadecimal to decimal and negative decimal, for low-resolution display dot patterns, display color values, and a number of 8-bit codes.

These tables are intended for convenient reference. This appendix is not intended as a tutorial for the materials discussed. The brief section introductions are for orientation only.

H.1 Bits and Bytes

This section discusses the relationships between bit values and their position within a byte. The following are some rules of thumb regarding the 65C02.

- A bit is a binary digit; it can be either a 0 or a 1.
- A bit can be used to represent any two-way choice. Some choices that a bit can represent in the Apple IIc are listed in Table H-1.

Table H-1. What a Bit Can Represent

Context	Representing	0 =	1 =
Binary number Logic	Place value Condition	0 False	1 x that power of 2 True
Any switch Any switch	Position Position	Off Clear†	On Set
Serial transfer Serial transfer Serial transfer Serial transfer Serial transfer	Beginning Data Parity End Communication state	Start 0 value SPACE BREAK	Carrier (no information yet) 1 value MARK Stop bit(s) Carrier
P reg. bit N P reg. bit V P reg. bit B P reg. bit D P reg. bit I P reg. bit Z P reg. bit C	Neg. result? Overflow? BRK command? Decimal mode? IRQ interrupts Zero result? Carry required?	No No No No Enabled No No	Yes Yes Yes Yes Disabled (masked out) Yes Yes

[†] Sometimes ambiguously termed reset .

- Bits can also be combined in groups of any size to represent numbers. Most of the commonly used sizes are multiples of four bits.
- Four bits comprise a nibble (sometimes spelled nybble).
- One nibble can represent any of 16 values. Each of these values is assigned a number from 0 through 9 and (because our decimal system has only ten of the sixteen digits we need) A through F.
- Eight bits (two nibbles) make a byte (Figure H-1).

Figure H-1. Bits, Nibbles, and Bytes

		High I	Nibble			Low N	libble	
	MSB 7	6	5	4	3	2	1	LSB 0
Hexadecimal Decimal	\$80 128	\$40 64	\$20 32	\$10 16	\$08	\$04 4	\$02 2	\$01
Binary	Hexadecimal		Decimal					
0000	9	0		0				
0001		1						
0010		2		2				
0011		3		1 2 3 4 5 6 7 8 9				
0100		4		4				
0101	S	5		5				
0110		6		6				
0111	\$	7		7				
1000		8		8				
1001		9						
1010		A		10				
1011		В		11				
1100		C		12				
1101		D		13				
1110		E		14				
1111	\$	F		15				

- One byte can represent any of 16 x 16 or 256 values. The value can be specified by exactly two hexadecimal digits.
- Bits within a byte are numbered from bit 0 on the right to bit 7 on the left.
- The bit number is the same as the power of 2 that it represents, in a manner completely analogous to the digits in a decimal number.
- One memory position in the Apple IIc contains one eight-bit byte of data.
- How byte values are interpreted depends on whether the byte is an instruction in a language, part or all of an address, an ASCII code, or some other form of data. Tables H-6 through H-13 list some of the ways bytes are commonly interpreted.

- Two bytes make a word. The sixteen bits of a word can represent any one of 256 x 256 or 65536 different values.
- The 65C02 uses a 16-bit word to represent memory locations. It can therefore distinguish among 65536 (64K) locations at any given time.
- A memory location is one byte of a 256-byte page. The low-order byte of an address specifies this byte. The high-order byte specifies the memory page the byte is on.

H.2 Hexadecimal and Decimal

Use Table H-2 for conversion of hexadecimal and decimal numbers.

Table H-2. Hexadecimal/Decimal Conversion

Digit	\$x000	\$0x00	\$00x0	\$000x
F	61440	3840	240	15
E	57344	3584	224	14
D	53248	3328	208	13
	49152	3072	192	12
СВ	45056	2816	176	11
A	40960	2560	160	10
9	36864	2304	144	9
8	32768	2048	128	8
7	28672	1792	112	7
6	24576	1536	96	6
5	20480	1280	80	- 5
4	16384	1024	64	4
3	12288	768	48	3
2	8192	512	32	2
1	4096	256	16	1

To convert a hexadecimal number to a decimal number, find the decimal numbers corresponding to the positions of each hexadecimal digit. Write them down and add them up.

Examples:

\$3C	=	?	FD47 = ?
\$30	=	48	\$F000 = 61440
\$0C	=	12	\$ D00 = 3328
			\$ 40 = 64
			\$ 7 = 7
\$3C	=	60	
			\$FD47 = 64839

To convert a decimal number to hexadecimal, subtract from the decimal number the largest decimal entry in the table that is less than it. Write down the hexadecimal digit (noting its place value) also. Now subtract the largest decimal number in the table that is less than the decimal remainder, and write down the next hexadecimal digit. Continue until you have zero left. Add up the hexadecimal numbers.

Example:

H.3 Hexadecimal and Negative Decimal

If a number is larger than decimal 32767, Applesoft BASIC allows and Integer BASIC requires that you use the negative-decimal equivalent of the number. Table H-3 is set up to make it easy for you to convert a hexadecimal number directly to a negative decimal number.

Table H-3. Decimal to Negative Decimal Conversion

Digit	\$x000	\$\$0x00	\$\$00x0	\$\$000x
F	0	0	0	-1
E	-4096	-256	-16	-2
D	-8192	-512	-32	-3
C	-12288	-768	-48	-4
В	-16384	-1024	-64	-5
	-20480	-1280	-80	-6
A 9 8 7	-24576	-1536	-96	-7
8	-28672	-1792	-112	-8
7	20072	-2048	-128	-9
6		-2304	-144	-10
6 5		-2560	-160	-11
4		-2816	-176	-12
3		-3072	-192	-13
2		-3328	-208	-14
1		-3584	-224	-15
0		-3840	-240	-16

To perform this conversion, write down the four decimal numbers corresponding to the four hexadecimal digits (zeros included). Then add their values (ignoring their signs for a moment). The resulting number, with a minus sign in front of it, is the desired negative decimal number.

Example:

To convert a negative-decimal number directly to a positive decimal number, add it to 65536. (This addition ends up looking like subtraction.)

Example:

To convert a negative-decimal number to a hexadecimal number, first convert it to a positive decimal number, then use Table H-2.

H.4 Graphics Bits and Pieces

Table H-4 is a quick guide to the hexadecimal values corresponding to 7-bit high-resolution patterns on the display screen. Since the bits are displayed in reverse order, it takes some calculation to determine these values. Table H-4 should make it easy.

The x represents bit 7. Zeros represent bits that are off; ones bits that are on. Use the first hexadecimal value if bit 7 is to be off, and the second if it is to be on.

For example, to get bit pattern 00101110, use \$3A; for 10101110, use \$BA.

Table H-4. Hexadecimal Values for High-Resolution Dot Patterns

Bit pattern	(x=0)	(x = 1
x0000000	\$00	\$80
x0000001	\$40	\$CO
x0000010	\$20	SAO
x0000011	\$60	\$E0
x0000100	\$10	\$90
x0000101	\$50	\$D0
x0000110	\$30	\$B0
x0000111	\$70	\$FO
x0001000	\$08	\$88
x0001001	\$48	\$C8
x0001010	\$28	\$A8
x0001011	\$68	\$E8
x0001100	\$18	\$98
x0001101	\$58	\$D8
x0001110	\$38	\$B8
x0001111	\$78	\$F8
x0010000	\$04	\$84
x0010001	\$44	\$C4
x0010010	\$24	\$A4
x0010011	\$64	\$E4

H.5 Peripheral Identification Numbers

Many Apple products now use Peripheral Identification Numbers (called **PIN numbers**) as shorthand for serial device characteristics. The Apple II Series *System Utilities Disk* presents a menu from which to select the characteristics of, say, a printer or modem. From the selections made, it generates a PIN for the user. Other products have a ready-made PIN that the user can simply type in.

Table H-5 is a definition of the PIN number digits. When communication mode is selected, the seventh digit is ignored.

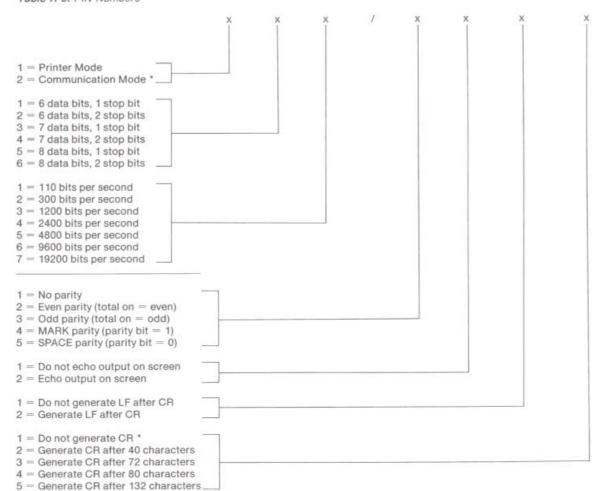

Example:

252/1111 means:

Communication mode 8 data bits, 1 stop bit 300 baud (bits per second)

No parity
Do not echo output to display
No linefeed after carriage return
Do not generate carriage returns

Table H-5. PIN Numbers

^{*} If you select Communication Mode, then seventh digit must equal 1. This value is supplied automatically when you use the UUD.

H.6 Eight-Bit Code Conversions

Tables H-6 through H-13 show the entire ASCII character set twice: once with the high bit off, and once with it on. Here is how to interpret these tables.

- The Binary column has the 8-bit code for each ASCII character.
- The first 128 ASCII entries represent 7-bit ASCII codes plus a high-order bit of 0 (SPACE parity or Pascal)—for example, 01001000 for the letter H.
- The last 128 ASCII entries (from 128 through 255) represent 7-bit ASCII codes plus a high-order bit of 1 (MARK parity or BASIC)—for example, 11001000 for the letter H.
- A transmitted or received ASCII character will take whichever form (in the communication register) is appropriate if odd or even parity is selected—for example, 11001000 for an odd-parity H, 01001000 for an even-parity
- The ASCII Char column gives the ASCII character name.
- The Interpretation column spells out the meaning of special symbols and abbreviations, where necessary.
- The What to Type column indicates what keystrokes generate the ASCII character (where it is not obvious). The numbers between columns refer to footnotes.
- The columns marked Pri and Alt indicate what displayed character results from each code when using the primary or alternate display character set, respectively. Boldface is used for inverse characters; italic is used for flashing characters.

Note that the values \$40 through \$5F (and \$C0 through \$DF) in the alternate character set are displayed as MouseText characters (Figure 5-1) if the firmware is set to do so (section 5.2.2), or if the firmware is bypassed.

Note: The primary and alternate displayed character sets in Tables H-6 through H-13 are the result of firmware mapping. The CHARGEN ROM actually contains only one character set. The firmware mapping procedure is described in section 3.36.

Glossary

65C02: The microprocessor used in the Apple IIc computer.

ACIA: Asynchronous Communications Interface Adapter. A single chip that converts data from parallel to serial form, and vice versa, and handles serial transmission and reception and RS-232-C signals, under the control of its internal registers set and changed by firmware or software.

accumulator: The register in the 6502 and 65C02 microprocessors where most computations are performed.

acronym: A word formed from the initial letters of a name or phrase, such as ROM, from read-only memory.

ADC: See analog-to-digital converter.

address: A number used to identify something, such as a location in the computer's memory.

analog: Represented in terms of a physical quantity that can vary smoothly and continuously over a range of values. For example, a conventional 12-hour clock face is an analog device that represents the time of day in terms of the angles of the clock's hands. Compare digital.

analog-to-digital converter: A device that converts quantities from analog to digital form. For example, the Apple IIc's hand control converts the position of the control dial (an analog quantity) into a discrete number (a digital quantity) that changes in steps even when the dial is turned smoothly.

AND: A logical operator that produces a true result if both of its operands are true, a false result if either or both of its operands are false; compare **OR**, **exclusive OR**, **NOT**.

Apple IIc: A personal computer in the Apple II family, manufactured and sold by Apple Computer, Inc.

Applesoft: An extended version of the BASIC programming language used with the Apple IIc computer. The firmware for interpreting and executing programs in Applesoft is included in the Apple IIc ROM.

ASCII: American Standard Code for Information Interchange; a code in which the numbers from 0 to 127 stand for text characters, used for representing text inside a computer and for transmitting text between computers or between a computer and a peripheral device.

assembler: A language translator that converts a program written in assembly language into an equivalent program in machine language.

assembly language: A low-level programming language in which individual machine-language instructions are written in a symbolic form more easily understood by a human programmer than machine language itself.

asserted: Made true (positive in positive-true logic; negative in negative-true logic).

asynchronous: Having a variable time interval between characters.

back panel: The rear face of the Apple IIc computer, which includes the power switch, the power connector, and connectors for two serial devices, a video display device, an external disk drive, and a mouse or hand control.

bandwidth: A measure of the range of frequencies a device can handle. In the case of a video monitor, greater bandwidth enables it to display more information; to display 80 columns of text, a monitor should have a bandwidth of at least 12 MHz.

base address: In indexed addressing, the fixed component of an address.

baud: A unit of signaling speed equal to the number of discrete conditions or signal events per second. Often equated (though not precisely) with bits per second.

binary: The representation of numbers in terms of powers of two, using the two digits 0 and 1. Commonly used in computers, since the values 0 and 1 can easily be represented in physical form in a variety of ways, such as the presence or absence of current, positive or negative voltage, or a white or black dot on the display screen.

bit: A binary digit (0 or 1); the smallest possible unit of information, consisting of a simple two-way choice, such as yes or no, on or off, positive or negative, something or nothing.

board: See printed-circuit board.

boot: To start up a computer by loading a program into memory from an external storage medium such as a disk. Often accomplished by first loading a small program whose purpose is to read the larger program into memory. The program is said to *pull itself up by its own bootstraps*.

bootstrap: See boot.

BREAK: A SPACE (0) signal sent over a communication line, of long enough duration to interrupt the sender. This signal is often used to end a session with a timesharing service.

BRK: A 65C02 instruction that causes the microprocessor to halt.

buffer: An area of the computer's memory used as a *holding* area where information can be stored by one program or device and then read out by another at a different speed.

bus: A group of wires that transmit related information from one part of a computer system to another. In the Apple IIc, the address bus has 16 wires, and the data bus has eight.

byte: A unit of information consisting of a fixed number of bits; on the Apple IIc, one byte consists of eight bits and can represent any value between 0 and 255.

carriage return: An ASCII character (decimal 13; Appendix H) that ordinarily causes a printer or display device to place the subsequent character on the left margin. On a manual typewriter, this movement is combined with line feed (the advancement of the paper to the next line). With computers, carriage return and line feed are separate, causing hair-raising problems for the user.

carrier: The background signal on a communication channel that is modified to *carry* the information. Under RS-232-C rules, the carrier signal is equivalent to a continuous MARK (1) signal; a transition to 0 then represents a start bit.

carry flag: The C bit in the 65C02 processor status register, used to hold the *carry bit* in addition and subtraction.

cathode-ray tube: An electronic device, such as a television picture tube, that produces images on a screen coated with phosphors that emit light when struck by a focused beam of electrons.

central processing unit: See processor.

character: A letter, digit, punctuation mark, or other symbol used in printing, displaying or transferring information.

character code: A number used to represent a text character for processing by a computer system.

chip: The small piece of semiconducting material (usually silicon) on which an integrated circuit is fabricated.

Clear To Send: An RS-232-C signal from a DCE to a DTE that is normally kept false until the DCE makes it true, indicating that all circuits are ready to transfer data out.

code: (1) A number or symbol used to represent some piece of information in a compact or easily processed form. (2) The statements or instructions making up a program.

cold start: The process of starting up the Apple IIc when the power is first turned on (or as if the power had just been turned on) by loading the operating system into main memory, then loading and running a program. Compare warm start.

command: A communication from the user to a computer system (usually typed from the keyboard) directing it to perform some action.

command character: An ASCII character, usually CONTROL-A or CONTROL-(i), that causes the serial port firmware to interpret subsequent characters as a command.

command register An ACIA location (at address \$C09A for port 1 and \$C0AA for port 2) that stores parity type and RS-232-C signal characteristics.

communication mode: An operating state in which serial port 2 (or 1, if so set) is prepared to exchange data and signals with a DCE (such as a modem).

compiler: A language translator that converts a program written in a high-level programming language into an equivalent program in some lower-level language (such as machine language) for later execution. Compare **interpreter**.

composite video: A video signal that includes both display information and the synchronization (and other) signals needed to display it.

computer: An electronic device for performing predefined (programmed) computations at high speed and with great accuracy.

computer system: A computer and its associated hardware, firmware, and software.

connector: A physical device such as a plug, socket, or jack, used to connect two devices to one another.

control character: A character that controls or modifies the way information is printed or displayed. Control characters have ASCII codes between \$00 and \$1F (or between \$80 and \$9F if the high-order bit is set). You can generate them at the Apple IIc keyboard by holding down CONTROL while typing one of the letter keys or © [\] ^ or _.

control register: An ACIA location (at address \$C09B for port 1, or \$C0AB for port 2) that stores data format and baud rate selections.

CPU: Central processing unit; see processor.

CRT: See cathode-ray tube.

cursor: A symbol displayed on the screen that marks where the user's next action will take effect or where the next character typed from the keyboard will appear.

DAC: See digital-to-analog converter.

data: Information; especially information used or operated on by a program.

data bit: One of five to eight bits representing a character.

Data Carrier Detect: An RS-232-C signal from a DCE (such as a modem) to a DTE (such as an Apple IIc) indicating that a communication connection has been established.

Data Communication Equipment: As defined by the RS-232-C standard, any device that transmits or receives information. Usually this is a modem. However, when a Modem Eliminator is used, the Apple IIc itself looks like a DCE to the other device, and the other device looks like a DCE to the Apple IIc.

data format: The form in which data is stored, manipulated or transferred. Serial data transmitted and received by port 1 or 2 has a data format of: one start bit, five to eight data bits, an optional parity bit, and one, one and a half, or two stop bits.

Data Set Ready: An RS-232-C signal from a DCE to a DTE indicating that the DCE has established a connection.

Data Terminal Equipment: As defined by the RS-232-C standard, any device that generates or absorbs information, thus acting as a terminus of a communication connection.

Data Terminal Ready: An RS-232-C signal from a DTE to a DCE indicating a readiness to transmit or receive data.

DCD: See Data Carrier Detect.

DCE: See Data Communication Equipment.

debug: To locate and correct an error or the cause of a problem or malfunction in a computer system. Typically used to refer to software-related problems.

decimal: The common form of number representation used in everyday life, in which numbers are expressed in terms of powers of ten, using the ten digits 0 to 9.

default: A value, action, or setting that is assumed or set in the absence of explicit instructions otherwise.

demodulate: To recover the information being transmitted by a modulated signal; for example, a conventional radio receiver demodulates an incoming broadcast signal to convert it into sound emitted by a speaker.

device: (1) A physical apparatus for performing a particular task or achieving a particular purpose. (2) In particular, a hardware component of a computer system.

digit: (1) One of the characters 0 to 9, used to express numbers in decimal form. (2) One of the characters used to express numbers in some other form, such as 0 and 1 in binary or 0 to 9 and A to F in hexadecimal.

digital: Represented in a discrete (noncontinuous) form, such as numerical digits. For example, contemporary digital clocks display the time in numerical form (such as 2:57) instead of using the positions of a pair of hands on a clock face. Compare analog.

digital-to-analog converter: A device that converts quantities from digital to analog form.

DIP: See dual in-line package.

disassembler: A language translator that converts a machine-language program into an equivalent program in assembly language, more easily understood by a human programmer. The opposite of an assembler.

disk: An information storage medium consisting of a flat, circular magnetic surface on which information can be recorded in the form of small magnetized spots, similarly to the way sounds are recorded on tape.

disk drive: A device that writes and reads information on the surface of a magnetic disk.

diskette: A term sometimes used for the small (5-1/4-inch) flexible disks used with the Apple Disk II drive.

Disk II drive: A model of disk drive made and sold by Apple Computer for use with the Apple IIe computer; uses 5-1/4-inch flexible (*floppy*) disks.

Disk Operating System: An optional software system for the Apple IIe that enables the computer to control and communicate with one or more Disk II drives.

display: (1) Information exhibited visually, especially on the screen of a display device. (2) To exhibit information visually. (3) A display device.

display device: A device that exhibits information visually, such as a television receiver or video monitor.

display screen: The glass or plastic panel on the front of a display device, on which images are displayed.

DOS: See Disk Operating System.

DSR: See Data Set Ready.

DTE: See Data Terminal Equipment.

DTR: See Data Terminal Ready.

dual in-line package: An integrated circuit packaged in a narrow rectangular box with a row of metal pins along each side; similar in appearance to an armored centipede.

echo: To send an input character to a video display, printer, or other output device.

225

edit: To change or modify; for example, to insert, remove, replace, or move text in a document.

editor: A program that enables the user to create and edit information of a particular form; for example, a *text editor* or a *graphics editor*.

effective address: In machine-language programming, the address of the memory location on which a particular instruction actually operates, which may be arrived at by indexed addressing or some other addressing method.

emulation mode: A manner of operating in which one computer or interface imitates another.

even parity: Use of an extra bit set to 0 or 1 as necessary to make the total number of 1 bits (among the data bits plus the parity bit) an even number.

error message: A message displayed or printed to notify the user of an error or problem in the execution of a program.

escape mode: A state of the Apple IIe computer, entered by pressing the (ESC) key, in which certain keys on the keyboard take on special meanings for positioning the cursor and controlling the display of text on the screen.

escape sequence: A sequence of keystrokes, beginning with (ESC), used for positioning the cursor and controlling the display of text on the screen.

exclusive OR: A logical operator that produces a true result if one of its operands is true and the other false, a false result if its operands are both true or both false; compare **OR**, **AND**, **NOT**.

execute: To perform or carry out a specified action or sequence of actions, such as those described by a program.

firmware: Software stored permanently in hardware: programs in read-only memory (ROM). Such programs (for example, the Applesoft interpreter and the Apple IIc Monitor program) are built into the computer at the factory; they can be executed at any time but cannot be modified or erased from main memory. Compare hardware, software.

fixed-point: A method of representing numbers inside the computer in which the decimal point (more correctly, the binary point) is considered to occur at a fixed position within the

number. Typically, the point is considered to lie at the right end of the number, so that the number is interpreted as an integer. Compare **floating-point**.

flexible disk: A disk made of flexible plastic; often called a floppy disk. Compare rigid disk.

floating-point: A method of representing numbers inside the computer in which the decimal point (more correctly, the binary point) is permitted to *float* to different positions within the number. Some of the bits within the number itself are used to keep track of the point's position. Compare **fixed-point**.

form feed: An ASCII character (decimal 12; Appendix H) that causes a printer or other paper-handling device to advance to the top of the next page.

framing error: In serial data transfer, absence of the expected stop bit(s) at the end of a received character. The serial port 1 and 2 ACIAs record this error by setting bit 1 (FRM) of its status register to 1. The ACIA checks and records each framing error separately: if the next character is OK, the FRM bit is cleared.

full duplex: Capable of simultaneous two-way communication.

graphics: (1) Information presented in the form of pictures or images. (2) The display of pictures or images on a computer's display screen. Compare **text**.

half duplex: Capable of communication in one direction at a time.

hand control: An optional peripheral device that can be connected to the Apple IIc's hand control connector and has a rotating dial and a pushbutton; typically used to control game-playing programs, but can be used in more serious applications as well.

hand control connector: A 9-pin connector on the Apple IIc's back panel, used for connecting hand controls to the computer.

hardware: Those components of a computer system consisting of physical (electronic or mechanical) devices. Compare software, firmware.

hertz: The unit of frequency of vibration or oscillation, also called cycles per second; named for the physicist Heinrich Hertz and abbreviated Hz. The Apple IIc's 65C02 microprocessor operates at a clock frequency of 1 million hertz, or 1 megahertz (MHz).

hexadecimal: The representation of numbers in terms of powers of sixteen, using the sixteen digits 0 to 9 and A to F. Hexadecimal numbers are easier for humans to read and understand than binary numbers, but can be converted easily and directly to binary form: each hexadecimal digit corresponds to a sequence of four binary digits, or bits.

high-level language: A programming language that is relatively easy for humans to understand. A single statement in a high-level language typically corresponds to several instructions of machine language.

high-order byte: The more significant half of a memory address or other two-byte quantity. In the Apple IIc's 65C02 microprocessor, the low-order byte of an address is usually stored first and the high-order byte second.

high-resolution graphics: The display of graphics on the Apple IIc's display screen as a six-color array of points, 280 columns wide and 192 rows high.

hold time: In computer circuits, the amount of time a signal must remain valid after some related signal has been turned off; compare **setup time**.

Hz: See hertz.

IC: See integrated circuit.

index: (1) A number used to identify a member of a list or table by its sequential position. (2) A list or table whose entries are identified by sequential position. (3) In machine-language programming, the variable component of an indexed address, contained in an index register and added to the base address to form the effective address.

indexed addressing: A method of specifying memory addresses used in machine-language programming.

index register: A register in a computer processor that holds an index for use in indexed addressing. The Apple IIc's 65C02 microprocessor has two index registers, called the X register and the Y register.

input: (1) Information transferred into a computer from some external source, such as the keyboard, a disk drive, or a modem. (2) The act or process of transferring such information.

instruction: A unit of a machine-language or assembly-language program corresponding to a single action for the computer's processor to perform.

integer: A whole number, with no fractional part; represented inside the computer in fixed-point form.

integrated circuit: An electronic component consisting of many circuit elements fabricated on a single piece of semiconducting material, such as silicon; see **chip**.

interface: The devices, rules, or conventions by which one component of a system communicates with another.

interpreter: A language translator that reads a program written in a particular programming language and immediately carries out the actions that the program describes. Compare **compiler**.

interrupt: A temporary suspension in the execution of a program by a computer in order to perform some other task, typically in response to a signal from a peripheral device or other source external to the computer.

inverse video: The display of text on the computer's display screen in the form of black dots on a white (or other single phosphor color) background, instead of the usual white dots on a black background.

I/O: Input/output; the transfer of information into and out of a computer. See input, output.

I/O device: Input/output device; a device that transfers information into or out of a computer. See input, output, peripheral device.

I/O link: A fixed location that contains the address of an input/output subroutine in the Apple IIc Monitor program.

K: Two to the tenth power, or 1024 (from the Greek root *kilo*, meaning one thousand); for example, 64K equals 64 times 1024, or 65,536.

keyboard: The set of keys built into the Apple IIc computer, similar to a typewriter keyboard, for typing information to the computer.

keystroke: The act of pressing a single key or a combination of keys (such as CONTROL)-C) on the Apple IIc keyboard.

kilobyte: A unit of information consisting of 1K (1024) bytes, or 8K (8192) bits; see **K**.

KSW: The symbolic name of the location in the Apple IIc's memory where the standard input link is stored; stands for *keyboard switch*. See I/O link.

language: See programming language.

language translator: A system program that reads a program written in a particular programming language and either executes it directly or converts it into some other language (such as machine language) for later execution. See interpreter, compiler, assembler.

least significant bit: The right-hand bit of a binary number as written down; it's positional value is 0 or 1.

line feed: An ASCII character (decimal 10; Appendix H) that ordinarily causes a printer or video display to advance to the next line.

load: To transfer information from a peripheral storage medium (such as a disk) into main memory for use; for example, to transfer a program into memory for execution.

local: Nearby; capable of direct connection using wires only.

location: See memory location.

logical operator: An operator, such as AND, that combines logical values to produce a logical result.

low-level language: A programming language that is relatively close to the form that the computer's processor can execute directly. Low-level languages available for the Apple IIc include 65C02 machine language and 65C02 assembly language.

low-order byte: The less significant half of a memory address or other two-byte quantity. In the Apple IIc's 65C02 microprocessor, the low-order byte of an address is usually stored first and the high-order byte second.

low-power Schottky: A type of TTL integrated circuit having lower power and higher speed than a conventional TTL integrated circuit.

low-resolution graphics: The display of graphics on the Apple IIc's display screen as a sixteen-color array of blocks, 40 columns wide and 48 rows high.

machine language: The form in which instructions to a computer are stored in memory for direct execution by the computer's processor. Each model of computer processor (such as the 65C02 microprocessor used in the Apple IIc) has its own form of machine language.

main memory: The memory component of a computer system that is built into the computer itself and whose contents are directly accessible to the processor.

MARK parity: A bit of value 1 appended to a binary number for transmission. The receiving device can then check for errors by looking for this value on each character.

memory: A hardware component of a computer system that can store information for later retrieval; see main memory, random-access memory, read-only memory, read-write memory.

memory location: A unit of main memory that is identified by an address and can hold a single item of information of a fixed size; in the Apple IIc, a memory location holds one byte, or eight bits, of information.

MHz: Megahertz; one million hertz. See hertz.

microcomputer: A computer, such as the Apple IIc, whose processor is a microprocessor.

microprocessor: A computer processor contained in a single integrated circuit, such as the 65C02 microprocessor used in the Apple IIc.

microsecond: One millionth of a second; abbreviated us.

millisecond: One thousandth of a second; abbreviated ms.

mode: A state of a computer or system that determines its behavior.

modem: Modulator/demodulator; a peripheral device that enables the computer to transmit and receive information over a telephone line; a DCE that connects a DTE to communication lines.

modem eliminator: The physical crossing of wires that replaces a pair of modems for direct connection of two DTEs.

modulate: To modify or alter a signal so as to transmit information; for example, conventional broadcast radio transmits sound by modulating the amplitude (amplitude modulation, or AM) or the frequency (frequency modulation, or FM) of a carrier signal.

monitor: See video monitor.

Monitor program: A system program built into the Apple IIc in firmware, used for directly inspecting or changing the contents of main memory and for operating the computer at the machine-language level.

most significant bit: The leftmost bit of a binary number as written down. This bit represents 0 or 1 times 2 to the power one less than the total number of bits in the binary number. For example, in the binary number 10000, which contains five digits, the 1 represents 1 times two to the fourth power—or sixteen.

nanosecond: One billionth (in British usage, one thousand-millionth) of a second; abbreviated ns.

network: A collection of interconnected, individually controlled computers, together with the hardware and software used to connect them.

nibble: A unit of information equal to half a byte, or four bits; can hold any value from 0 to 15. Sometimes spelled *nybble*.

NOT: A unary logical operator that produces a true result if its operand is false, a false result if its operand is true; compare **AND, OR, exclusive OR**.

NTSC: (1) National Television Standards Committee; the committee that defined the standard format used for transmitting broadcast video signals in the United States. (2) The standard video format defined by the NTSC.

object code: See object program.

object program: The translated form of a program produced by a language translator such as a compiler or assembler; also called object code. Compare **source program**.

odd parity: Use of an extra bit set to 0 or 1 as necessary to make the total number of 1 bits an odd number.

opcode: See operation code.

operand: A value to which an operator is applied; the value on which an opcode operates.

operating system: A software system that organizes the computer's resources and capabilities and makes them available to the user or to application programs running on the computer.

operation code: The part of a machine-language instruction that specifies the operation to be performed; often called **opcode**.

operator: A symbol or sequence of characters, such as + or AND, specifying an operation to be performed on one or more values (the operands) to produce a result.

OR: A logical operator that produces a true result if either or both of its operands are true, a false result if both of its operands are false; compare **exclusive OR**, **AND**, **NOT**.

output: Information transferred from a computer to some external destination, such as the display screen, a disk drive, a printer, or a modem.

overrun: A condition that occurs when the Apple IIc processor does not retrieve a received character from the ACIAs receive data register before the subsequent character arrives. The ACIA automatically sets bit 2 (OVR) of its status register; subsequent characters are lost. The receive data register contains the last valid data word received.

page: (1) A screenful of information on a video display, consisting on the Apple IIc of 24 lines of 40 or 80 characters each. (2) An area of main memory containing text or graphical information being displayed on the screen. (3) A segment of main memory 256 bytes long and beginning at an address that is an even multiple of 256 bytes.

page zero: See zero page.

parallel interface: An interface in which many bits of information (typically eight bits, or one byte) are transmitted simultaneously over different wires or channels. Compare serial interface.

parity: Maintenance of a sameness of level or count, usually the count of 1 bits in each character, for error checking.

parity error: Absence of the correct parity bit value in a received character. The serial port ACIAs record this error by setting bit 0 (PAR) of their status registers to 1.

PC board: See printed-circuit board.

phase: (1) A stage in a periodic process; a point in a cycle; for example, the 65C02 microprocessor uses a clock cycle consisting of two phases called PHI0 and PHI1. (2) The relationship between two periodic signals or processes; for example, in NTSC color video, the color of a point on the screen is expressed by the instantaneous phase of the video signal relative to the color reference signal.

pipelining: A feature of a processor that enables it to begin fetching the next instruction before it has finished executing the current instruction. All other things equal, processors that have this feature run faster than those without it.

pointer: An item of information consisting of the memory address of some other item.

pop: To remove the top entry from a stack.

port: The point of connection, usually a physical connector, between a computer and a peripheral device, another computer, or a network.

power supply: The hardware component of a computer that draws electrical power from a power outlet and converts it to the forms needed by some other hardware component.

printed-circuit board: A hardware component of a computer or other electronic device, consisting of a flat, rectangular piece of rigid material, commonly fiberglass, from which all conducting material except the desired circuits is etched, and to which integrated circuits and other electronic components are connected.

processor: The hardware component of a computer that performs the actual computation by directly executing instructions represented in machine language and stored in main memory.

program: (1) A set of instructions describing actions for a computer to perform in order to accomplish some task, conforming to the rules and conventions of a particular programming language. (2) To write a program.

programming language: A set of rules or conventions for writing programs.

prompt: To remind or signal the user that some action is expected, typically by displaying a distinctive symbol, a reminder message, or a menu of choices on the display screen.

prompt character: A text character displayed on the screen to prompt the user for some action. Often also identifies the program or component of the system that is doing the prompting; for example, the prompt character] is used by the Applesoft BASIC interpreter, > by Integer BASIC, and * by the system Monitor program.

prompt message: A message displayed on the screen to prompt the user for some action.

protocol: A predefined exchange of control signals between devices enabling them to prepare for and carry out coordinated data transfers.

push: To add an entry to the top of a stack.

radio-frequency modulator: A device for converting the video signals produced by a computer to a form that can be accepted by a television receiver.

RAM: See random-access memory.

random-access memory: Memory in which the contents of individual locations can be referred to in an arbitrary or random order.

raster: The pattern of parallel lines making up the image on a video display screen. The image is produced by controlling the brightness of successive dots on the individual lines of the raster.

read: To transfer information into the computer's memory from a source external to the computer (such as a disk drive or modem) or into the computer's processor from a source external to the processor (such as the keyboard or main memory).

read-only memory: Memory whose contents can be read but not written; used for storing firmware. Information is written into read-only memory once, during manufacture; it then remains there permanently, even when the computer's power is turned off, and can never be erased or changed. Compare read-write memory, random-access memory, write-only memory.

read-write memory: Memory whose contents can be both read and written; often misleadingly called *random-access memory*, or *RAM*. The information contained in read-write memory is erased when the computer's power is turned off, and is

Glossary 235

permanently lost unless it has been saved on a more permanent storage medium, such as a disk. Compare **read-only memory**, **random-access memory**, **write-only memory**.

receive data register: A read-only register in each serial port ACIA (at location \$C098 for port 1 and \$C0A8 for port 2) that stores the most recent character successfully received.

register: A location in a computer processor where an item of information, such as a byte, is held and modified under program control. Registers in the 65C02 microprocessor include the accumulator (A), two index registers (X and Y), the stack pointer (S), the processor status register (P), and the program counter (PC). The PC register holds two bytes (sixteen bits); the other registers hold one byte (eight bits) each.

remote: Too distant for direct connection using wires or cables only.

Request To Send: An RS-232-C signal from a DTE to a DCE to prepare the DCE for data transmission.

return address: The point in a program to which control returns on completion of a subroutine.

RF modulator: See radio-frequency modulator.

RI: See Ring Indicator.

rigid disk: A disk made of a hard, nonflexible material. Compare flexible disk.

Ring Indicator: An optional RS-232-C signal from a DCE to a DTE that indicates the arrival of a call.

ROM: See read-only memory.

routine: A part of a program that accomplishes some task subordinate to the overall task of the program.

RS-232-C: A standard created by the Electronic Industries Association (EIA) to allow devices of different manufacturers to exchange serial data—particularly via telephone lines.

RTS: See Request To Send.

run: (1) To execute a program. (2) To load a program into main memory from a peripheral storage medium, such as a disk, and execute it.

save: To transfer information from main memory to a peripheral storage medium for later use.

screen: See display screen.

scroll: To change the contents of all or part of the display screen by shifting information out at one end (most often the top) to make room for new information appearing at the other end (most often the bottom), producing an effect like that of moving a scroll of paper past a fixed viewing window. See viewport, window.

serial interface: An interface in which information is transmitted sequentially, one bit at a time, over a single wire or channel. Compare **parallel interface**.

setup time: The amount of time a signal must be valid in advance of some event; compare **hold time**.

silicon: A non-metallic, semiconducting chemical element from which integrated circuits are made.

soft switch: A means of changing some feature of the Apple IIc from within a program; specifically, a location in memory that produces some special effect whenever its contents are read or written.

software: Those components of a computer system consisting of programs that determine or control the behavior of the computer. Compare **hardware**, **firmware**.

source code: See source program.

source program: The original form of a program given to a language translator such as a compiler or assembler for conversion into another form; sometimes called *source code*. Compare **object program**.

space character: A text character whose printed representation is a blank space, typed from the keyboard by pressing the SPACE bar.

SPACE parity: A bit of value 0 appended to a binary number for transmission. The receiving device can look for this value on each character as a means of error checking.

stack: A list in which entries are added or removed at one end only (the top of the stack), causing them to be removed in LIFO (last-in-first-out) order.

start bit: A transition from a MARK signal to a SPACE signal for one bit-time, indicating that the next string of bits represents a character.

Glossary 237

status register: A register in an ACIA (at location \$C099 for port 1 and \$C0A9 for port 2) that stores the state of two of the RS-232-C signals and the state of the transmit and receive data registers, as well as the outcome of the most recent character transfer.

stop bit: A MARK signal following a string of data bits (or their optional parity bit) to indicate the end of a character.

string: An item of information consisting of a sequence of text characters.

strobe: (1) An event, such as a change in a signal, that triggers some action. (2) A signal whose change is used to trigger some action.

subroutine: A part of a program that can be executed on request from any point in the program, and which returns control to the point of the request on completion.

television receiver: A display device capable of receiving broadcast video signals (such as commercial television) by means of an antenna. Can be used in combination with a radio-frequency modulator as a display device for the Apple IIc computer. Compare **video monitor**.

television set: See television receiver.

terminal: A device consisting of a typewriterlike keyboard and a display device, used for communicating between a computer system and a human user. Personal computers such as the Apple IIc typically have all or part of a terminal built into them.

terminal mode: An operating state of the Apple IIc communication port in which the firmware makes the computer act like a simple ASCII terminal.

text: (1) Information presented in the form of characters readable by humans. (2) The display of characters on the Apple IIc's display screen. Compare **graphics**.

text window: An area on the Apple IIc's display screen within which text is displayed and scrolled.

transistor-to-transistor logic: (1) A family of integrated circuits used in computers and related devices. (2) A standard for interconnecting such circuits that defines the voltages used to represent logical zeros and ones.

transmit data register: A write-only register in one of the serial port ACIAs (at location \$C098 for port 1 and \$C0A8 for port 2) that holds the current character to be transmitted.

troubleshoot: To locate and correct the cause of a problem or malfunction in a computer system. Typically used to refer to hardware-related problems; compare **debug**.

TTL: See transistor-to-transistor logic.

unary operator: An operator that applies to a single operand; for example, the minus sign (–) in a negative number such as –6 is a unary arithmetic operator.

user: The person operating or controlling a computer system.

user interface: The rules and conventions by which a computer system communicates with the person operating it.

vector: (1) The starting address of a program segment, when used as a common point for transferring control from other programs. (2) A memory location used to hold a vector, or the address of such a location.

video: (1) A medium for transmitting information in the form of images to be displayed on the screen of a cathode-ray tube. (2) Information organized or transmitted in video form.

video monitor: A display device capable of receiving video signals by direct connection only, and which cannot receive broadcast signals such as commercial television. Can be connected directly to the Apple IIc computer as a display device. Compare television receiver.

viewport: All or part of the display screen, used by an application program to display a portion of the information (such as a document, picture, or worksheet) that the program is working on. Compare window.

warm start: The process of restarting the Apple IIc after the power is already on, without reloading the operating system into main memory and often without losing the program or information already in main memory. Compare cold start.

window: The portion of a collection of information (such as a document, picture, or worksheet) that is visible in a viewport on the display screen; compare viewport.

word: A group of bits of a fixed size that is treated as a unit; the number of bits in a word is a characteristic of each particular computer.

Glossary 239

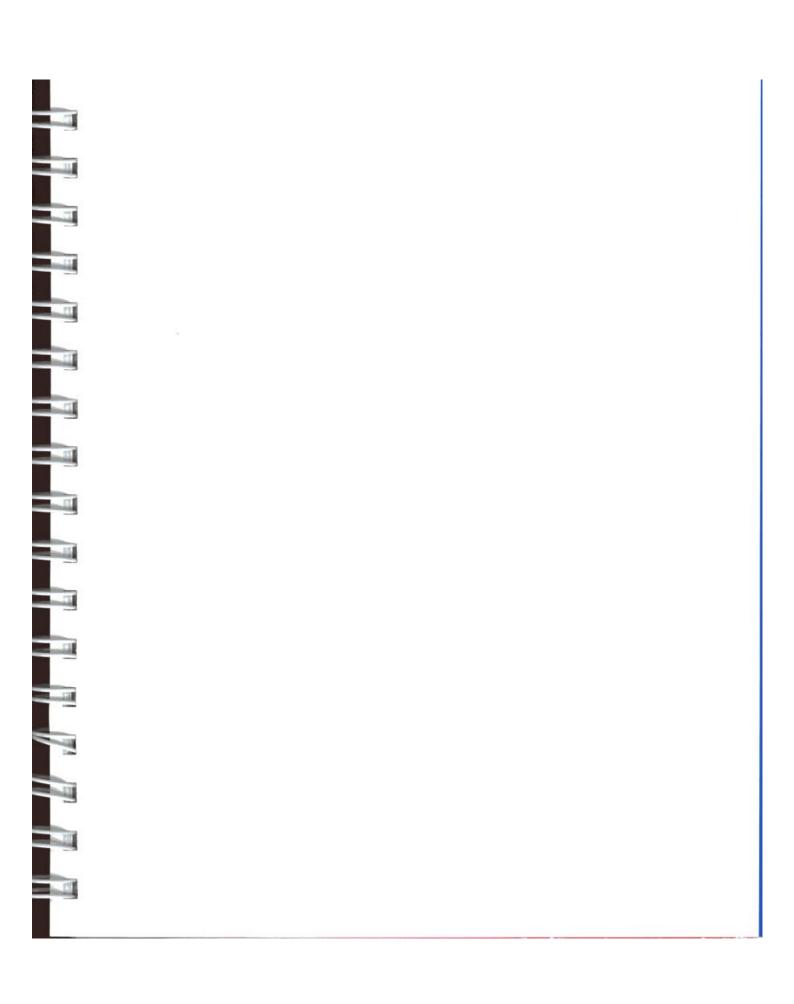

wraparound: The automatic continuation of text from the end of one line to the beginning of the next, as on the display screen or a printer.

write: To transfer information from the computer to a destination external to the computer (such as a disk drive, printer, or modem) or from the computer's processor to a destination external to the processor (such as main memory).

X register: One of the index registers in the 65C02 microprocessor.

Y register: One of the index registers in the 65C02 microprocessor.

zero page: The first page (256 bytes) of the Apple IIc's memory, also called *page zero*. Since the high-order byte of any address in this page is zero, only the low-order byte is needed to specify a zero-page address; this makes zero-page locations more efficient to address, in both time and space, than locations in any other page of memory.

Bibliography

Apple II Monitors Peeled. Cupertino, Calif.: Apple Computer, Inc., 1978.

Currently not updated for Apple IIe and IIc, but a good introduction to Apple II series input/output procedures; also useful for historical background.

- Apple Ile Design Guidelines. Cupertino, Calif.: Apple Computer, Inc., 1982.
- Addendum to the Design Guidelines. Cupertino, Calif.: Apple Computer, Inc., 1984.
